OPERATIONS

OF THE

BUREAU OF ANIMAL INDUSTRY

FOR THE

FISCAL YEAR ENDED JUNE 30,

1906.

FEBRUARY 20, 1907.

Referred to the Committee on Agriculture
and ordered to be printed.

WASHINGTON:
GOVERNMENT PRINTING OFFICE.

1907.

LETTERS OF TRANSMITTAL.

To the Senate and House of Representatives:

I transmit herewith the report of the operations of the Bureau of Animal Industry of the Department of Agriculture for the fiscal year ending June 30, 1906, in compliance with the requirements of section 11 of the act approved May 29, 1884, for the establishment of that Bureau.

THEODORE ROOSEVELT.

THE WHITE HOUSE,
February 16, 1907.

DEPARTMENT OF AGRICULTURE,
OFFICE OF THE SECRETARY,
Washington, D. C., February 15, 1907.

The PRESIDENT:

I have the honor to submit herewith, for transmittal to Congress, a report of the operations of the Bureau of Animal Industry of this Department for the fiscal year ended June 30, 1906, in compliance with the requirements of section 11 of the act approved May 29, 1884, for the establishment of that Bureau.

Very respectfully,•

JAMES WILSON,
Secretary.

OPERATIONS OF THE BUREAU OF ANIMAL INDUSTRY FOR THE FISCAL YEAR ENDED JUNE 30, 1906.

INTRODUCTION.

For the first two and a half months of the fiscal year covered by this report the work of the Bureau was under the direction of Dr. D. E. Salmon as chief and for the remainder of the period it has been in charge of Dr. A. D. Melvin. Doctor Salmon, after continuous service in the position of chief for more than twenty-one years, beginning with the organization of the Bureau in 1884, resigned that position early in September, 1905, and his resignation was accepted to take effect November 1. Doctor Melvin, who was assistant chief at the time of Doctor Salmon's resignation, was in charge of the Bureau work as acting chief from the middle of September (when Doctor Salmon relinquished the active management in order to complete some special work before his retirement), and was appointed chief on December 1.

THE MEAT INSPECTION.

The meat inspection, as in previous years, has been the largest branch of the Bureau's work. In this service more than half the members of the Bureau force were engaged and more than half the appropriation for the year was expended.

As the conditions at the Chicago stock yards and packing houses have been so prominently before the public during recent months, it may be well to point out certain facts regarding the meat-inspection service as conducted by the Bureau.

Until the passage of the new meat-inspection law, on the last day of the fiscal year (June 30, 1906), the inspection was carried on under the act of March 3, 1891, as amended by the act of March 2, 1895. That law provided for—

1. The inspection of all live cattle which were intended for export or whose carcasses or products were intended for export.

2. (a) The mandatory ante-mortem inspection of cattle, sheep, and hogs which were subjects of interstate commerce and which were about to be slaughtered at slaughterhouses, canning, salting, packing, or rendering establishments in any State or Territory, the carcasses or products of which were to be transported and sold for human consumption in any other State or Territory or the District of Columbia.

- (b) The additional permissive post-mortem examination of carcasses of all cattle, sheep, and hogs about to be prepared for human consumption at any slaughterhouse, canning, salting, packing, or

rendering establishment in any State or Territory or the District of Columbia and which were the subjects of interstate commerce.

In other words, the ante-mortem inspection was made mandatory, while the post-mortem examination was only discretionary.

Some of the defects and limitations of this law should be noted to give an idea of the disadvantages under which the inspection has been conducted. In the first place, the law required the ante-mortem inspection of all cattle, sheep, and swine slaughtered at certain classes of establishments, the carcasses or products of which were to enter interstate commerce, but no specific provision was made for funds with which to perform this work, and the annual appropriation has never been sufficient to enable the Bureau to cover all establishments carrying on an interstate business. Indeed, many establishments which applied for inspection had to be refused on account of lack of money to carry on the work.

While the law authorized the marking of meats and products which on inspection were found free from disease and wholesome, and prohibited the interstate shipment of meats and products found diseased and unwholesome, it made no provision and gave no authority for marking and rendering unfit for food purposes the diseased and unwholesome carcasses and products. As a matter of fact, however, it has long been the practice of the Bureau to require the destruction of all condemned carcasses and parts, though in case of the refusal of the proprietor to comply with such orders there was no remedy except to withdraw inspection.

It is very doubtful whether the law gave any authority for following up meats after they had once been inspected and passed immediately after slaughter, or for condemning any such meat which might afterwards become unwholesome or unclean before or during the process of canning or packing or before being placed on the market. But whether the law gave any such authority or not is a purely academic question, since the lack of funds made it impossible to extend the inspection to cover all the processes of curing, canning, packing, etc. No authority whatever to control the sanitation of the establishments or to prevent adulteration or the use of chemicals and preservatives was given by the law.

The inspection was therefore practically confined to the ante-mortem inspection of animals and the inspection of the carcasses immediately after slaughter. The meat found free from disease and otherwise wholesome at the time of this post-mortem inspection was properly marked and that found diseased or unwholesome was destroyed. There is no question that this inspection was efficient as far as it went and that it went as far as the law and the limited appropriations allowed. In fact, as hereinbefore and hereinafter shown, the Bureau in its efforts to maintain an efficient inspection sometimes even went so far as to assume authority not conferred by law. In all the recent agitation the wholesomeness of the inspected fresh meat has not been seriously called into question. The disclosures of unsatisfactory conditions have related almost wholly to the canned and prepared meats, the use of preservatives, and the insanitary condition and methods of the packing establishments—matters over which the Bureau has had no control whatever under the law.

About the latter part of the year 1905 a number of articles criticising the inspection methods and the insanitary conditions at the Chicago

stock yards and packing houses began to appear in certain medical journals and other publications. The subject was considered in the Department, and it was determined that the best way to get at the matter was to send a competent committee to Chicago to make an investigation. This was finally decided on about the middle of February, but on account of illness the committee was unable to get away until early in March. This committee, consisting of Dr. John R. Mohler, chief of the pathological division of this Bureau; Dr. R. P. Steddom, chief of the inspection division of the Bureau, and Mr. George P. McCabe, Solicitor of the Department, made a thorough investigation, and presented an exhaustive report under date of April 3. This report was promptly transmitted to the President, and has been printed as a Congressional document.

Without waiting to send a committee to investigate and report, however, two orders regarding sanitation were issued in February. The Department Solicitor advised that, while such regulations were very necessary, the Department had no legal authority to enforce them; but it was decided to issue them nevertheless and to enforce them if possible. The first of these orders, issued February 8, 1906, to Bureau inspectors in charge of meat inspection, required that trucks and other receptacles used in handling tuberculous carcasses and parts thereof should not be used for any purposes other than handling condemned material and offal; also that all knives and other implements used, as well as the hands of the inspector, and the packing-house implements, should be washed in an antiseptic solution. Bichloride of mercury tablets were furnished for this purpose.

The other order regarding sanitation was as follows:

[Amendment No. 5 to B. A. I. Order No. 125.]

RULES AND REGULATIONS FOR THE INSPECTION OF LIVE STOCK AND THEIR PRODUCTS.

U. S. DEPARTMENT OF AGRICULTURE,
OFFICE OF THE SECRETARY,
Washington, D. C., February 14, 1906.

It is hereby ordered, That section 4 of B. A. I. Order No. 125 be, and the same is hereby amended by the addition of the following:

Sanitation.—(e) Official establishments shall be kept in a clean and sanitary condition. Ceilings, side walls, pillars, partitions, etc., shall, whenever practicable, be frequently whitewashed; where this is impracticable they shall, when necessary, be washed, scraped, or otherwise effectually cleaned; likewise all trucks and other receptacles used in moving, mixing, storing, or curing meat or meat products shall be frequently cleaned, and beef carriers or other employees who handle meat in contact with their clothing shall be required to keep such clothing in a sanitary condition. Separate, suitably ventilated, and otherwise sanitary toilet rooms and rooms for the reception of clothing of employees shall be provided and so located that the odors therefrom do not penetrate the rooms or compartments in which meat or meat products are prepared, cured, stored, packed, or otherwise handled; all such rooms or compartments (except the killing floors) shall be provided with cuspidors, and employees who expectorate shall be required to use them.

JAMES WILSON, *Secretary*.

On receipt of the committee's report showing the conditions which existed at Chicago, the inspector in charge at that station was directed to take steps for the improvement of these conditions, and a traveling inspector was sent to Chicago to assist in this work. On April 9 an order was issued to all inspectors in charge of meat inspection, stating that the report of the committee had revealed some conditions which

must be improved at once, and directing them to see that all requirements of the meat-inspection regulations were rigidly enforced and to report any establishment which failed to comply with any part of the regulations. On May 22 the inspectors in charge of the principal stations were instructed to report whether amendment 5, regarding sanitation, was being complied with, and to notify the proprietors of the establishments that lavatories must be installed, so that workmen could have no excuse for not keeping their hands clean, and that proprietors must see that employees did keep themselves clean. It was also ordered that meat must be raised from the floors, and that the practice of mixing meats upon the floors must be abandoned and suitable boxes or benches provided; also that wire netting and other covers for racks, vats, and boxes used for meats and meat products must be provided.

The weak points and the limitations of the laws under which the meat inspection has heretofore been conducted have long been realized, and several times in the past recommendations have been made by the Secretary of Agriculture and the chief of the Bureau for the enactment of new laws and the increase of appropriations in order to extend the inspection and improve its efficiency. On two or three occasions bills to remedy some of the defects in the law have been introduced in Congress, but they failed of passage.

The new law of June 30, 1906, commonly known as the meat-inspection amendment to the agricultural appropriation act, greatly enlarges the powers of the Secretary of Agriculture and makes a permanent annual appropriation of \$3,000,000 to pay the cost of meat inspection. With the additional authority and money thus granted the service will be greatly extended and strengthened. The inspection is being extended as rapidly as possible to establishments which are engaged in interstate or foreign business and come within the law, and the inspection is applied not only to the live animals before slaughter and to the carcasses immediately after slaughter, but afterwards to the meats and meat-food products in all the stages and processes of preparation, curing, canning, etc. Sanitary equipment, conditions, and methods are required, the use of harmful chemicals and preservatives and of misleading labels is prohibited, and the transportation of meat in interstate and foreign commerce is being regulated. Regulations covering these various points have been issued.

WORK OF THE YEAR.

During the fiscal year 1906 inspection was inaugurated at 23 establishments. One of these had previously had inspection, but had been destroyed by fire; the remaining 22, located in 13 different cities, were establishments that had not theretofore had inspection. Inspection was not conducted during the fiscal year, for various causes, at 11 establishments which had had inspection in the previous fiscal year. Of the 13 cities, 6 were cities in which Federal inspection had not been previously conducted. Below are shown the number of establishments and the number of cities where inspection has been conducted during each fiscal year since 1891:

Number of establishments and cities where meat inspection has been conducted, 1891 to 1906.

Fiscal year.	Number of establishments.	Number of cities.	Fiscal year.	Number of establishments.	Number of cities.
1891.....	9	6	1899.....	139	42
1892.....	23	12	1900.....	149	46
1893.....	37	16	1901.....	157	52
1894.....	46	17	1902.....	155	50
1895.....	55	19	1903.....	156	50
1896.....	102	26	1904.....	152	51
1897.....	128	33	1905.....	151	52
1898.....	135	35	1906.....	163	58

The following statement shows the number of ante-mortem inspections of animals intended for slaughter, an increase of 4.69 per cent over the figures reported for the previous fiscal year:

Ante-mortem inspections for the fiscal year 1906.

Kind of animals.	For official abattoirs in cities where inspections were made.	For other cities and miscellaneous buyers.	Total inspections.	Rejected (subject to result of post-mortem inspection).	
				At abattoirs.	In stock yards.
Cattle.....	7,045,353	6,462,494	13,507,847	1,875	47,307
Sheep.....	8,221,977	7,072,004	15,293,981	921	6,763
Calves.....	1,036,895	651,851	1,688,746	460	13,979
Hogs.....	26,026,484	12,393,513	38,419,997	5,864	83,474
Total.....	42,330,709	26,579,862	68,910,571	9,120	151,523

The following table shows the number of regular post-mortem inspections made, and indicates an increase of 6.66 per cent over the previous fiscal year. The condemnations show an increase of 33.82 per cent over the previous year, due largely to the closer lines of inspections for tuberculosis.

Post-mortem inspections for the fiscal year 1906.

Kind of animals.	Number of inspections.			Carcasses condemned.			
	For official abattoirs.	On animals rejected in stock yards.	Total inspections.	For official abattoirs.	Of animals rejected in stock yards.	Total.	Parts of carcasses condemned.
Cattle.....	6,887,001	38,525	6,925,526	16,659	3,780	20,439	4,016
Sheep.....	8,219,605	4,025	8,223,630	4,990	817	5,807	123
Calves.....	1,100,220	2,555	1,102,775	3,432	1,419	4,851	89
Hogs.....	26,580,964	68,389	26,649,353	121,243	6,613	127,856	121,931
Total.....	42,787,790	113,494	42,901,284	146,324	12,629	158,953	126,159

In addition to the carcasses condemned on regular and microscopic examinations, others were tanked as follows:

Carcasses of animals found dead or killed by local inspectors and tanked.

Manner of death.	Cattle.	Sheep.	Calves.	Hogs.	Total.
Died in yards.....	477	543	229	1,282	2,531
Killed in yards by local inspectors.....	417	164	6,694	10,537	17,812
Died at abattoirs.....	390	2,340	218	11,940	14,888
Total.....	1,284	3,047	7,141	23,759	35,231

The various diseases and conditions for which carcasses and parts were condemned and tanked during the year are shown in detail in the following table, which also includes animals found dead and those killed by local inspectors:

Diseases and conditions for which condemnations were made, fiscal year 1906.

Cause of condemnation.	Cattle.		Sheep.		Calves.		Hogs.	
	Car-casses.	Parts.	Car-casses.	Parts.	Car-casses.	Parts.	Car-casses.	Parts.

Total.....	21,723	4,016	8,821	123	11,992	89	151,615	121,931

The following table, showing the growth of the post-mortem inspection since it was first inaugurated, indicates that the number of inspections made the past year was the largest in the history of the Bureau:

Number of animals inspected at slaughter for abattoirs having inspection, 1891 to 1906.

Fiscal year.	Cattle.	Calves.	Sheep.	Hogs.	Horses.	Total.
1891.....	83,889	83,889
1892.....	3,167,009	59,089	583,361	3,809,459
1893.....	3,922,079	92,947	870,512	4,885,538
1894.....	3,861,594	96,331	1,020,764	7,648,146	12,626,835
1895.....	3,704,042	116,093	1,428,601	13,616,539	18,865,275
1896.....	3,985,484	256,905	4,629,796	14,250,191	23,122,376
1897.....	4,242,216	273,124	5,209,161	16,808,771	26,533,272
1898.....	4,418,738	244,330	5,496,904	20,893,199	31,053,171
1899.....	4,382,020	246,184	5,603,096	23,836,943	3,332	34,071,575
1900.....	4,841,166	315,693	6,119,886	23,336,884	5,559	34,619,188
1901.....	5,219,149	413,830	6,639,212	24,642,753	1,992	36,916,936
1902.....	5,559,969	555,836	7,434,878	25,277,107	1,649	38,829,439
1903.....	6,134,410	668,855	8,585,960	21,793,738	344	37,183,307
1904.....	6,350,011	764,590	8,261,051	24,128,462	39,504,114
1905.....	6,096,597	845,862	7,872,671	25,323,984	40,139,114
1906.....	6,925,526	1,102,775	8,223,630	26,649,353	42,901,284

The meat-inspection brand or label was placed upon 24,163,869 quarters of beef, 8,154,490 carcasses of sheep, 1,094,946 carcasses of calves, and 939,656 carcasses of hogs. Sacks and barrels of meat were sealed as follows: Beef, 123,470; pork, 1,120,955.

White meat-inspection stamps, indicating the regular post-mortem inspection, were affixed to packages of meat and meat products as follows:

Beef.....	7,684,116
Mutton.....	32,701
Veal.....	2,437
Pork.....	15,940,227
Total.....	23,659,481

The number of cars sealed containing inspected meats and meat products was 76,956.

The movement of inspected meats between official establishments is shown in the following table. A large amount of work was involved in supervising the shipment of this meat and in identifying it on arrival.

Movement of inspected meat between official establishments.

Class.	Number of quarters and carcasses.	Smaller pieces. (weight).
Beef.....	Quarters. 1,904,056	Pounds. 179,345,864
Mutton.....	Carcasses. 24,103	4,982,206
Veal.....	86,884	816,449
Pork.....	31,556	459,311,407

CERTIFICATES OF INSPECTION OF MEATS FOR EXPORT.

There were 42,784 certificates of ordinary inspection issued to cover meats and meat products for export as follows: 1,304,923 quarters, 9,597 pieces, 787 carcasses, and 1,598,229 packages of beef, weighing 390,291,533 pounds; 42 carcasses and 20,482 packages of mutton, weighing 609,373 pounds; 3,788 carcasses and 646,103 packages of pork, weighing 201,453,171 pounds; a grand total of 592,354,077 pounds.

The following table shows, by years, beginning with 1898, the quantities of the different classes of meat for the exportation of which certificates of ordinary inspection were issued:

Quantities of meat for export under certificates of ordinary inspection, 1898 to 1906.

Fiscal year.	Beef.	Mutton.	Pork.
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
1898.....	339,650,091	324,996	244,956,482
1899.....	360,843,856	525,705	278,696,435
1900.....	438,138,233	680,897	272,050,663
1901.....	452,830,373	894,648	231,144,938
1902.....	416,990,762	1,145,248	188,360,011
1903.....	371,920,737	2,729,013	133,122,610
1904.....	419,058,781	712,089	154,442,440
1905.....	361,012,062	206,570	155,513,776
1906.....	390,291,533	609,373	201,453,171

The total cost of the work of ordinary meat inspection was \$789,263.76.

THE MICROSCOPIC INSPECTION OF PORK.

The number of hog carcasses examined for trichinæ was 536,997, classified as follows: Class A (free from all appearance of trichinæ), 523,945, being 97.57 per cent; class B (containing trichinalike bodies or disintegrating trichinæ), 6,220, being 1.16 per cent; class C (containing live trichinæ), 6,832, being 1.27 per cent.

The number of trichinous carcasses disposed of was 6,926, weighing 1,613,365 pounds, 47.24 per cent of which was tanked, the remainder being converted into cooked meat products.

The number of certificates issued for microscopically inspected pork was 3,104, covering 68,689 stamped packages containing 26,566,409 pounds of pork and pork products.

The following table shows, by years, the quantity of pork exported since 1892 to countries requiring microscopic inspection. The increase of 1906 over 1905 was 80.45 per cent.

Quantities of pork exported to countries requiring microscopic inspection, 1892 to 1906.

Fiscal year.	Pounds.	Fiscal year.	Pounds.	Fiscal year.	Pounds.	Fiscal year.	Pounds.
1892.....	22,025,698	1896.....	21,497,321	1900.....	55,809,626	1904.....	9,020,521
1893.....	8,059,758	1897.....	42,570,572	1901.....	35,942,404	1905.....	14,721,935
1894.....	18,845,119	1898.....	120,110,356	1902.....	33,681,229	1906.....	26,566,409
1895.....	39,355,230	1899.....	108,858,149	1903.....	19,108,341		

The cost of microscopic inspection was \$63,297.94, being an average of 11.79 cents for each carcass examined and 0.24 cent for each pound exported.

INSPECTION OF VESSELS AND EXPORT ANIMALS.

Seven hundred and forty-nine vessels carrying live stock were inspected before clearance. The number of certificates of inspection issued for American cattle exported to Europe was 1,312.

The following table shows the number of inspections of live animals for export and the number exported during the year:

Number of inspections of American and Canadian animals for export, number rejected, and number exported, fiscal year 1906.

Kind of animals.	American animals.			Canadian animals.		
	Number of inspections. ^a	Number rejected.	Number exported.	Number inspected.	Number rejected.	Number exported.
Cattle.....	805,045	1,516	^b 416,372	46,874	11	46,863
Sheep.....	137,824	93	^c 67,340	27,282	25	27,257
Horses.....	1,393	1,252	6	6

^a The apparent discrepancy between the figures of this column and those of the two following columns is due to the fact that a large proportion of the animals were inspected more than once, thus making the number of inspections considerably larger than the actual number of animals, and that in a few cases part of the animals inspected and passed for export were diverted and slaughtered in this country by the owners.

^b 34,181 via Canada.

^c 4,314 via Canada.

All animals included in the foregoing statement as exported were shipped to Great Britain except 7,981 cattle and 77 horses to Belgium, 110 horses to Germany, and 150 horses to France.

Other animals were exported as follows: 2,597 cattle, 1,360 sheep, 21 horses, 144 mules, and 1,061 swine, of which 1,193 cattle and 1,153 sheep were destined to Bermuda, 130 cattle to Barbados, 1,345 cattle to Brazil; 30 cattle, 56 swine, and 11 horses to Argentina; 9 cattle to Mexico, 1 bull to British Guiana, 77 sheep to the West Indies, 1 horse to Jamaica, 100 mules to Cuba; 11 cattle, 1,005 swine, 44 mules, and 9 horses to Hawaii, and 8 cattle to Lower California.

The following table shows the number of animals inspected on landing at the three British ports where the Bureau maintains inspection and to which the greater part of the exports go, also the number and percentage lost in transit. It will be observed that under the Bureau's supervision of this traffic the percentage of loss is very low.

Number of animals inspected at time of landing in London, Liverpool, and Glasgow, and the loss in transit, fiscal year 1906.

Total.....	419,730	665	.158	90,853	610	.666	908	9	.991

Special certificates of health were issued for the exportation of 2,830 cattle, 309 hogs, and 5 goats.

Tuberculin tests were made on 447 cattle in order to meet the requirements of the countries to which they were intended to be exported. Of these cattle 410 passed and 37 were rejected.

The total cost of the Bureau work in connection with the exportation of live animals was \$49,349.22.

INSPECTION AND QUARANTINE OF IMPORTED ANIMALS.

In order to exclude from this country the contagion of the destructive animal diseases which exist in other parts of the world it is necessary to use the utmost vigilance with regard to imported animals. The perfection of the system of inspection and quarantine maintained on the Atlantic coast gives great protection to that section. Inspection is also maintained along the Canadian and Mexican borders, and arrangements are made for quarantine at certain points. As the Department refuses to permit the importation of animals from the Orient, owing to the great prevalence of dangerous animal diseases there, and as the importation of all kinds of animals from the Philippines is prohibited by Executive order for the same reason, no importations are permitted on the Pacific seaboard from across the seas. In spite of these precautions, however, there appears to be a possibility of contagion being brought in with forage or straw used as packing in China, or surreptitiously by pet animals. It is believed that the importation of forage from China and the use of hay or straw in packing goods for shipment from that country to the United States should be prohibited. There is especial danger that surra may be brought in by dogs from the Philippines, though the customs authorities have shown vigilance in preventing this.

All animals offered for importation are required to be inspected, and certain kinds, when coming from certain countries, are in addition required to be quarantined for a sufficient period to insure their freedom from contagion.

The following table shows the number of imported animals inspected and quarantined, and the number admitted on inspection without quarantine, during the fiscal year:

Imported animals inspected, with or without quarantine, fiscal year ended June 30, 1906.

In addition to its regular quarantine stations at Athenia, N. J., Littleton, Mass., and Halethorp, Md., for the ports of New York, Boston, and Baltimore, respectively, the Bureau in June, 1905, secured control of Simonson's Island, an isolated point located on the Fresh Kills, a tributary of Staten Island Sound, as a place of special quarantine in cases where more complete isolation of the animals

was desirable. This arrangement was first made for the quarantine of milch goats imported from Switzerland, under an agreement whereby the owner was to accept a per capita fee, to be paid by the importers, as a rental or compensation, the importer likewise paying for the necessary feed, bedding, and animal attendants, under the rule governing the quarantine of animals. A similar agreement has been made for another year. This island was used for the quarantine of 139 head of goats in October, 1905, 35 head of goats in May, 1906, and 51 head of cattle in June, 1906.

The quarantine stations on the Atlantic seaboard, with the exception of that at Halethorp (near Baltimore), are in a satisfactory condition. At the latter station most of the buildings are in a dilapidated condition, and for the purposes of the port of Baltimore the station is not suitably located. The ground immediately adjoining is being surveyed for a race course, and this will further render the station unsuitable for quarantine purposes, as it would be impossible to keep away from the quarantine grounds the people who would frequent the race track as employees and visitors. These circumstances will in all probability soon make it imperative to abandon the present station and find a new location. It is hoped that a location may be secured on the water front of the Patapsco River, which will permit the unloading of animals directly from steamers or barges to a wharf on the quarantine ground. Some investigations have been made of land so located, and it seems probable that satisfactory arrangements can be made for the use of such land. In order to equip the new station with buildings and inclosures, however, an appropriation will be absolutely necessary.

TUBERCULIN TEST IN GREAT BRITAIN.

For the convenience of importers of fine breeding cattle the Bureau has continued making tuberculin tests in England and Scotland of cattle intended for importation into the United States. The results of these tests during the fiscal year are shown in the following table:

Results of tuberculin tests in England and Scotland of cattle for importation.

CONTROL OF CONTAGIOUS DISEASES.

The work of the Bureau for the control and eradication of contagious diseases has continued. This work during the past fiscal year, as heretofore, has consisted of the maintenance of a quarantine of the section infected with Texas or southern cattle fever and the

supervision of the movement of cattle from that section to points above the quarantine line; also the eradication of sheep scab, cattle mange, scabies in horses, and a venereal disease of horses known as *maladie du coït*.

TEXAS FEVER.

During the quarantine season of 1905 there were received at live-stock centers 47,496 carloads of cattle shipped for immediate slaughter from points below the quarantine line, the whole number of such cattle being 1,279,453. There were also inspected in the noninfected areas of Texas and Oklahoma 125,225 head of cattle which were permitted to be moved north for purposes other than immediate slaughter. Supervision was exercised over 100,916 dippings in crude petroleum, and over the cleaning and disinfection of 42,510 cars. The total cost of this work was \$45,984.81.

SHEEP SCAB.

In some States there has been a slight increase in sheep scab, but taken as a whole the condition is decidedly encouraging. The proportion of infected sheep during the past year was $5\frac{1}{2}$ per cent of those inspected, while during the previous year it was $7\frac{1}{2}$ per cent.

In Arizona the conditions are decidedly improved and the percentage of disease is less than in former years. Idaho, Utah, and Wyoming also show a decided improvement. During the fiscal year just closed the ratio of infected sheep in those States was 1 in 43, while for the previous year it was 1 in 14. It is expected that conditions in Utah and Wyoming will soon be such that the Department can remove the quarantine from those States. From a survey of the entire field there is cause for the belief that this disease is being gradually brought under control.

During the fiscal year the total number of inspections of sheep for scabies was 59,246,288, and the total number of dippings was 12,396,976, of which 1,661,020 were redippings.

The total cost of this work was \$181,414.39.

The following table shows the number of inspections and dippings of sheep for scabies, and cars cleaned and disinfected, 1900 to 1906:

	Fiscal year.						
	1900.	1901.	1902.	1903.	1904.	1905.	1906.

Dippings.....	626, 838	1, 034, 368	1, 017, 162	2, 167, 002	9, 578, 476	16, 873, 659	12, 396, 976
Cars cleaned and disinfected.....			791	752	2, 732	7, 965	8, 625

CATTLE MANGE.

During the fiscal year the Bureau, in cooperation with State and Territorial officials, has made rapid progress in the extermination of mange in cattle. The State of Washington and Oregon and large portions of the States of Kansas, Colorado, Wyoming, and Texas, and of the Territories of New Mexico and Oklahoma have been released

from quarantine. The disease is being successfully controlled and eradicated in extensive areas in North Dakota, South Dakota, Wyoming, and Texas, and the early release of these areas from quarantine may be expected.

The total number of inspections of cattle for scabies during the fiscal was 14,983,260, and the total number of dippings was 243,826, of which 24,688 were redippings.

The total cost of this work was \$83,108.46.

The following table shows the number of inspections and dippings of cattle for scabies, and cars cleaned and disinfected, by fiscal years, from 1904 to 1906:

	Fiscal year.		
	1904.	1905.	1906.
Inspections.....	1,124,321	14,085,267	14,983,260
Dippings.....	162,554	563,394	243,826
Cars cleaned and disinfected.....	532	29,897	19,992

SCABIES IN HORSES.

The total number of inspections of horses for scabies was 27,507, and the total number of dippings was 690.

VENEREAL DISEASE OF HORSES.

The insidious venereal disease of horses known as *maladie du coït*, or dourine, which has existed in portions of South Dakota, Nebraska, and Iowa, is believed to have been practically eradicated as a result of several years' vigilant work by the Bureau. During the past fiscal year 965 inspections were made, and only 3 cases were found that were considered sufficiently suspicious for condemnation—1 stallion and 2 mares. Neither of the latter showed lesions characteristic of the disease on post-mortem examination. The stallion was killed by the owner and had been buried several days before the inspector reached the place, when it was too late to make a conclusive post-mortem examination. Animals that may possibly have been exposed to the disease will be kept under close observation, and any reports of suspected cases will be promptly investigated until sufficient time has elapsed to warrant confidence that the eradication is complete.

TEXAS FEVER INVESTIGATIONS AND TICK ERADICATION.

Special attention has been given during the year to the study of the disease commonly known as Texas fever, of the life history of the tick which transmits this fever, and of the methods for eradicating these fever ticks, in view of the proposed campaign for the eradication of the ticks from the infected section. For the purpose of giving information to the public on this subject two bulletins (Bureau Bulletin No. 78 and Farmers' Bulletin No. 258) have been prepared by Dr. John R. Mohler, chief of the Pathological Division, and issued during the year.

The act of Congress approved June 30, 1906, appropriated \$82,500 to enable the Secretary of Agriculture to undertake experimental

work in cooperation with State authorities in eradicating the ticks transmitting southern cattle fever. Anticipating this appropriation, the Bureau took up with the various State and Territorial authorities the subject of eradicating the ticks, with a view to ascertaining whether or not the laws and regulations of the various States and Territories would permit of conducting a vigorous campaign against the fever tick. It was found that, while some State laws afford ample provisions, other States either have no law bearing on the subject or the statutes are inadequate. It is urged that such laws be enacted by the different States in the infected area as will enable close cooperation between this Bureau and the State in the work of eradicating cattle ticks. The State and Territorial laws should give to local officers authority to enter premises, to inspect live stock, and to enforce the necessary quarantine and disinfection. The laws should also give authority to the proper State officials to issue rules and regulations and to confer authority upon Federal representatives to act as officials of the State in such matters. Funds should also be provided for the employment of local inspectors.

The Bureau also made plans to place additional inspectors in the field and to cooperate with the local officials in the different infected localities in an endeavor to exterminate cattle ticks by the various methods, and this work has since been taken up actively along the quarantine line from Virginia to California. It may be stated that as a result of the work of the last six months of 1906 it is believed that 40 whole counties and parts of 11 other counties, with an area larger than that of the State of Virginia, may safely be released from quarantine. By directing the principal efforts from the quarantine line southward it is believed that the infested territory can be gradually reduced and the line pushed farther south from year to year. It should be understood, however, that the complete eradication of the ticks from the entire section is an undertaking of great magnitude and difficulty and one that will require several years for its accomplishment.

Experiments have been conducted at the Bureau Experiment Station near Washington, D. C., also in Virginia, and, with the cooperation of the South Carolina Experiment Station, at Clemson, S. C., regarding the life history of the Texas fever tick and the exact time required for the tick to live parasitically on the cattle as well as the length of time it can exist without a host. As a result of these investigations several methods for the eradication of ticks, which have been found to be satisfactory for the States in which they were tried and under the climatic conditions met during the experiments, have been recommended in the bulletins mentioned.

Besides the six methods already published, there have been several combinations of these methods tried on certain farms with entirely satisfactory results. Thus, on one Virginia farm where the conditions were not such as to warrant the use of any one of the outlined plans in its entirety, a combination was suggested which has succeeded in completely ridding the cattle and premises of ticks. The 16 dairy cattle were removed from the infected pasture on September 10 and then placed on a cultivated field, where they were soiled. All ticks were carefully removed by hand three times weekly and burned. In this manner no tick was permitted to mature or to drop off during the egg-producing age. The cattle, which soon became tick free,

were not placed on the original pasture until May 1, by which time it had also become free of ticks, and it has remained so.

A somewhat similar combination proved successful on another dairy farm in Virginia. The infected cattle were taken from one pasture early in June, 1905, and placed on a second pasture, from which they were moved September 11 to a cultivated field, where they were hand picked three times weekly. As no noninfected pasture was available and it was not desirable to go to the expense of fencing the field, these cattle were kept free of ticks by hand picking and by mopping with crude petroleum that portion of the skin usually infested with ticks, and were continued on this cultivated land until fall, when they were placed in a barn which had been previously well disinfected with a chloride of lime solution and the barnyard cleaned of all manure, litter, and other harborers of ticks and eggs. The following spring the two pastures, which in all probability were by that time free of ticks, were nevertheless burned off for the sake of safety, and the cattle were placed thereon in April, and have since given no indication of becoming tick infested.

Experiments relative to the dropping off of ticks from cattle in feed lots were tried at the Bureau Experiment Station, also in Virginia and South Carolina, and the results were published in Bulletin No. 78.

The cooperative work being done in South Carolina consists of two demonstrations which have for their object the eradication of the Texas fever ticks from Oconee and Pickens counties. One demonstration has for its basis the known fact that the adult tick drops off the cattle to lay its eggs, after which it dies, and the young ticks can never reach maturity unless they gain access to the body of a host animal, in the absence of which animal they perish after varying lengths of time. The method being followed on one large farm heavily infested with ticks consists in pasture rotation, in the operation of which the original pasture is divided into two by a double line of fence about June 1, and the cattle are moved into one half, where they remain until September 10, after which they are moved three times at intervals of twenty days to fresh tick-free land from which the crops have been gathered. The cattle are then free from ticks, and on November 10 they are moved to the half of the original pasture which had been kept free of animals since June 1, by which time all the ticks it contained will have perished. By the following May all ticks on the other half will also have disappeared, both farm and cattle will be free of ticks, and the double line of fence can be removed. The second demonstration consists in the location of all the infected farms in the above-mentioned counties, and in hand mopping all the cattle on these infected farms in the fall with Beaumont crude petroleum to catch the last crop of ticks, and a similar treatment at the beginning of spring to kill all of those ticks which have survived the winter. This method has been followed with very satisfactory results, and the possibility of applying the same mode of treatment to cattle on large ranches by dipping with the view of destroying the last crop of ticks in the fall and the first crop in the spring is now receiving consideration.

In the practical operation of any method already outlined, or a combination of two or more of these methods, it is to be hoped that the Bureau will receive the cooperation as well as the support of all

southern agriculturists, which is so essential if the ultimate object of tick eradication is to be obtained. And there is small use of one farmer or set of farmers freeing their lands and cattle of the parasites if their lands and cattle are to be constantly exposed to the danger of reinfestation from the ticks of their immediate nonprogressive neighbors.

A simultaneous experiment with the same generation of ticks has been inaugurated at the Bureau Experiment Station and at the South Carolina Experiment Station in order to determine if the first crop of ticks is less virulent than later crops or if the cattle in the cooler spring months are not so susceptible as in the hot summer months, but this experiment has not been concluded.

A considerable amount of work was done by the Bureau station in an attempt to discover a more satisfactory method than that in common use for the production of immunity in cattle against Texas fever. The method now in use is unfortunate in that it frequently causes quite severe disease and occasionally the death of the treated animals. The experiments have not progressed sufficiently to merit more than a simple reference to them.

Further investigations have been made relative to the persistence of the parasite of Texas fever in the blood of southern cattle after their removal from all sources of fresh infection or reinfection and the significance of this persistence. A report on these investigations, also a general article on the southern cattle tick, have been prepared for publication in the Twenty-second Annual Report of the Bureau.

TUBERCULOSIS.

EXPERIMENTS IN IMMUNIZING CATTLE.

A number of prominent investigators, both in this country and in Europe, have recently been testing and recommending various methods for the protective inoculation of cattle against tuberculosis. Their systems of operation are mainly based upon similar processes; that is, they all inject the cattle with tubercle bacilli of either human or bovine origin. There is, however, considerable variation in the manner of administering the injections and also in the number of applications considered necessary to produce adequate protection for the animal, and there is also a difference in the preferred age at which the cattle are to be treated. In order that the most promising of these methods for immunizing cattle against tuberculosis might be tested and that new features which are greatly to be desired and which are lacking in present methods might be perfected and proved, some comparative experiments have been conducted by the Pathological Division with the cooperation of the Experiment Station. A number of calves have been inoculated in a variety of ways and with differing amounts of living tubercle organisms from varied sources. Numerous check animals are also being used, and these, with the several lots of test cattle, will later be subjected to exposure to virulent tubercle bacilli. The lot of cattle showing the greatest proportion of resistant animals at the completion of this experiment will be selected as representing the most feasible and effective method of immunizing cattle against tuberculosis. It is very desirable that perfect protection be afforded the cattle, if possible, by a single in-

oculation of the protective virus. It is therefore one of the aims of the present work to select cultures possessing the greatest degree of virulence compatible with safety to the animals treated, and at the same time to select some part of the animal's body as the seat of the injection that is but little liable to convey the micro-organisms to the glandular system, where they might readily cause the establishment of a generalized case of the very disease which it is so desirable to guard against. Owing to the slow development of tuberculosis naturally, no absolute selection of the best from among these various methods of protection can be made until the animals have proved by long exposure their ability to withstand the attacks of the tubercle bacilli.

TUBERCULOSIS IN HOGS.

Another phase of the subject of tuberculosis which has received a great deal of study by the Pathological Division is the increase in the number of tuberculous hogs received at abattoirs where Federal inspection is maintained. The records of the post-mortem inspectors at the various packing houses have been examined with a view to ascertaining the geographical location of the most serious centers of the disease, and at the same time tabulated forms have been prepared which show at a glance the proportion of cases in which the disease is limited to the throat of the hog, those where the lesions are localized but are established elsewhere than in the throat, and finally the proportion of serious generalized cases. It has been found that approximately 92 per cent of the 96,000 hogs thus reported tuberculous were affected in the cervical glands, and that some 30 per cent of these had no other lesion. The necessity of careful inspection of each head at the time of slaughter needs no further demonstration.

An effort has been made by the Pathological Division in conjunction with the Experiment Station to discover the most probable source of infection of these animals. It has been found that wherever tuberculous hogs are marketed from a farm the cows of that farm are tuberculous, or else the hogs have been fed upon skim milk or separator refuse from some public creamery to which the milk of tuberculous cows, or perhaps of but a single tuberculous cow, is delivered. Separator sediment has been obtained from several suspected creameries, and animal inoculations and microscopic examinations have demonstrated the presence of tubercle bacilli in 25 per cent of the samples of such refuse, thus proving the necessity of guarding calves and pigs from this source of infection. Such milk may be sterilized by warming to 176° F. (or 80° C.). One instance of serious infection was discovered, where the tuberculous cattle which originally brought the disease to the ranch had been destroyed. Still the disease persisted in attacking on an average some 24 per cent of the hogs marketed from the place during the following three years. Investigation then showed that the brood sows, which had been retained for some time, were badly infected and that they served as sources of tubercular contamination to each succeeding generation of pigs.

The investigations during the past year have therefore included the infection of sucking pigs through the tuberculous mammae of their mothers. Other hogs have been exposed to infection by following tuberculous cattle, where they had full access to all excretions from

them; others have been fed with tuberculous milk, and still others have been penned with cattle that were being fed upon tubercle bacilli of artificial cultivation in order that the infectiveness of the bacilli after passage through the alimentary tracts of the cattle might be observed. It was shown that hogs readily contract tuberculosis from eating the feces of tuberculous cattle and that this is probably one of the commonest causes of tuberculosis among hogs. Hogs were found invariably to show tuberculous disease of the lymph glands located at the angles of the jaws when infection reached their bodies through ingestion. Tubercle bacilli given cattle in their drinking water were found to pass through the entire length of their digestive apparatus and to appear in their feces without having lost the power to produce tuberculous disease. This last fact indicates that animals with tuberculous lungs, while they do not expectorate after coughing up tuberculous material, nevertheless scatter bacilli freely, by swallowing them, having them pass through their intestines and discharging them with their feces.

Experiments in the application of the tubercular test to hogs were also made in connection with the above studies, and it was shown that, if the proper precautions are taken, the diagnostic value of tuberculin with hogs is as great as with cattle. A method of procedure which was reliable in 97 per cent of the animals tested has been found. Bulletin No. 88, which contains full information upon these subjects, has just been issued.

OTHER EXPERIMENTS WITH TUBERCULOSIS.

It was shown by the investigations of the Experiment Station that the locations of lesions in the bodies of animals affected with tuberculosis is no guide as to the mode of infection, and that pulmonary disease is the most frequent form in which tuberculosis occurs is not necessarily because the commonest mode of infection is through the respiration, but more probably because of the relation of the lymphatic stream to the venous circulation and the filtration by the lung of the venous blood after the lymph has been poured into it and before it reaches any other organ.

Guinea pigs, which are generally regarded as extremely susceptible to tuberculosis, irrespective of the manner in which they are brought in contact with the infection, were found to possess a high degree of immunity when the infectious material entered their bodies through ingestion in the form of artificially infected milk. The contrary was shown to be true of hogs, which were found to be very susceptible to ingested infection of the kind that failed to injure the guinea pigs. It should be added that the immunity of guinea pigs to ingested tuberculous infection has a parallel in a similar immunity possessed by them to respired infection. Among many hundreds confined for varying periods of time during the last ten years in a small one-room animal hospital, which contained tuberculous guinea pigs at all times and for long periods of time, also tuberculous monkeys and rabbits, only one guinea pig is known to have contracted tuberculosis. This one animal became affected with what may be called, to distinguish it from artificially induced disease, naturally acquired tuberculosis through the intensest kind of exposure. It was one of three young produced in a small cage containing six adult females affected with

generalized tuberculosis. The tuberculous mother nursed this and the other two young, which remained healthy.

To injected tuberculous infection, quite independent of the character of the injection, guinea pigs have always been found to possess the high susceptibility with which they are commonly credited. This subject has been gone into at some length because it is of considerable importance in view of the extent to which guinea pigs are used by investigators in their studies of tuberculosis.

The examination of the feces of a number of tuberculous cattle showed that they are frequently very rich in acid-fast bacteria; that is, bacteria which have the microscopic appearance of and conduct themselves precisely like tubercle bacilli in the presence of various reagents. Such acid-fast bacteria could not be detected in the feces of the station cattle that are free from tuberculosis. In two cases, with the feces of two tuberculous cows, the acid-fast bacteria were definitely proved by inoculation tests to be tubercle bacilli. That the feces of tuberculous cattle may contain innumerable virulent tubercle bacilli must be regarded as a seriously important fact.

Cultures of tubercle bacilli which have been used since 1902 for the study of the transformation of characteristics of tubercle bacilli following their long-continued cultivation under artificial conditions have been kept under observation in the Pathological Division during the year, and the changes which have occurred in them have been noted.

Tubercle bacilli have been recovered from several rare animals at the National Zoological Park, such as the rattlesnake, the camel, the beaver, kangaroo rats, and the roughed or crab-eating fox, and it is of interest to note that these animals suffer from natural infections with tuberculosis, and that in most instances the micro-organisms present conform to the human type of tubercle bacilli.

DISTRIBUTION OF TUBERCULIN.

The demand for tuberculin, which is prepared in the Biochemic Division and furnished free of charge by the Bureau to authorized health officers in the various States and cities, greatly increased during the past year. The total amount of tuberculin prepared and shipped during the year was 103,510 doses, an increase of approximately 40 per cent over the amount sent out during the previous fiscal year.

HOG CHOLERA INVESTIGATIONS.

In the previous annual report the results of the experiments concerning the etiology of hog cholera were briefly described. The Biochemic Division, in pursuing this work further during the past fiscal year, has demonstrated that the filterable virus which has already been shown to be the primary cause of hog cholera in southwestern Iowa is also present in outbreaks of that disease occurring in eastern Nebraska, in central Iowa, and in Virginia. The outbreaks which have been studied in these localities possessed all of the well-known characteristics of hog cholera. These experiments demonstrated that the filterable virus is not peculiar to hog cholera as it is found in southwestern Iowa, and they also indicated that this virus was widely distributed and probably the active causative agent of all outbreaks

of that disease. A number of experiments having for their object the determination of the mode of transmission of the disease, the portal of entry of the virus into the hog's body, the length of life of the virus outside of the hog's body, and the nature of the virus itself, have been carried out, and the results will all be published later in bulletin form.

In connection with the other experiments the bactericidal action of hog's blood has been investigated and the results are now ready for publication. It is very gratifying to note that these recent experiments have substantiated in every way the results published in Bulletin No. 72.

In addition to the work just described, a certain number of experiments concerning the production of immunity from hog cholera have been arrived at, these immunity experiments being based upon the recently demonstrated fact (see Bulletin No. 72, Bureau of Animal Industry) that the primary cause of hog cholera exists in the blood of hogs sick of that disease, but not in pure cultures of *Bacillus cholerae suis*, which had previously been regarded as the cause of hog cholera. In a general way, the methods employed may be said to embrace the following general principles:

- (1) The injection of hogs immune from hog cholera with blood from hogs sick of that disease.

- (2) The drawing of blood from the immune hog hyperimmunized by injections of diseased blood, and the use of this immune blood, either alone or in conjunction with diseased blood, for immunizing healthy hogs or treating those sick of hog cholera.

By methods based on these principles we have secured from each of three different immunes, treated with different strains of diseased blood, sera which in doses of 10 c. c. to 20 c. c. afforded complete protection to nonimmune hogs against an infection which was fatal to from 70 to 100 per cent of untreated animals.

In view of these favorable results the process was patented in such a manner as to insure to all the people in the United States the right to its use free of any royalty, the patent being taken out in this way by Dr. M. Dorset, chief of the Biochemic Division, who planned and directed the investigations. The number of experiments thus far carried out is not considered sufficient to warrant the present recommendation of this process for general use, but further experiments are being pushed as rapidly as is consistent with thoroughness, and it is hoped that a detailed statement of the results obtained may be made during the present year.

Experiments in the prevention of hog cholera by selective breeding are being continued with the object of developing by artificial selection a race of hogs which will possess partial or complete immunity from hog cholera. This work, which is carried on by the Biochemic Division in cooperation with the Experiment Station, was begun several years ago, naturally immune hogs being used as a basis and each litter exposed to infection. Thus there were retained out of each litter only those animals which showed the greatest powers of resistance. Several generations of animals have been exposed to disease during the last two or three years and the work is still being carried on, but sufficient results have not been obtained to warrant an expression of opinion as to the final outcome.

GLANDERS.

During the year isolated outbreaks of glanders have been reported from various quarters, and material from suspected cases has been forwarded to the pathological laboratory for examination and diagnosis. Nasal secretions and tissues from horses were received from North Dakota, Connecticut, Maryland, Virginia, and the District of Columbia. The samples from Connecticut proved negative for glanders, but positive results were obtained from all other sources. Cases occurring in the District of Columbia come directly under the supervision of the Chief of the Bureau of Animal Industry, who directs the disposition of the animals, the isolation and testing of exposed animals, and the disinfection of the premises.

Of very great importance for the diagnosis of glanders is the Gruber-Widal reaction, first recommended by MacFadyean in 1896, which has been made use of during the past few years. It has been employed in a number of cases quite successfully, but up to the present time has not been used as a routine measure, as the character of most of the specimens received makes it necessary to rely for diagnosis either upon the Strauss inoculation method or the isolation of the specific bacillus itself. The Strauss method, in our hands, has also given excellent results, and but for the time required would be an ideal means of diagnosis.

The serum diagnosis (or the Gruber-Widal test) of glanders consists in the addition of fixed, definite quantities of blood serum from the suspected animals to young cultures of the *Bacillus mallei*, and, if the case be positive, results in an agglutination or aggregation of the isolated bacilli into small clumps, which eventually cling to the side or drop to the bottom of the tube of culture medium in which they have previously been held in suspension.

DISTRIBUTION OF MALLEIN.

The Bureau has continued to furnish mallein free of charge to authorized health officers and to the War Department, and during the fiscal year 10,105 doses, prepared by the Biochemic Division, were so distributed. This represents an increase of about 40 per cent over the distribution of the preceding fiscal year.

BLACKLEG.

The great demand for blackleg vaccine still continues, thus showing the confidence of the stock raiser in the efficacy of vaccinating his young cattle for the prevention of spontaneous outbreaks of this virulent disease. During the year there have been prepared in the Pathological Division and distributed among stock owners 1,350,915 doses of vaccine.

The results of inoculations for the year ending June 30, 1905, as reported to the Bureau by the stock raisers who have used the vaccine are as follows:

Results obtained from vaccine distributed during the fiscal year ended June 30, 1905.

State or Territory.	Number of reports.	Number of cattle vaccinated.	Deaths same season previous to vaccination.		Died after vaccination.					
			Number.	Per cent.	Within 48 hours.	From 2 to 7 days after.	Within 1 year.	Number of cases due to mistakes.	Total number.	Percentage of deaths.

After eliminating the number of cattle which die within forty-eight hours after vaccination as a result of being already infected with blackleg at the time of injection, and those whose death has been due to mistakes in performing the operation, the number of cases that died after vaccination is reduced to 3,575, or 0.48 per cent, whereas the losses without the use of vaccine were formerly as high as 10 or 12 per cent of the calves produced annually in the infected districts.

RABIES.

Within the District of Columbia there has been a considerable reduction in the frequency of cases of rabies during the past year. Of the 30 suspected cases examined in the laboratory of the Pathological Division from all sources, 16 proved positive, of which number only 8 came from within the District, as compared with 13 for a similar period of time last year, or a reduction of 38 per cent. In the following table the source and species of the animals affected

and the result of the experimental animal inoculations and microscopic examination of the plexiform ganglia, together with the number of persons or animals bitten, are given:

Results of inoculation tests and microscopic examination for rabies.

Date.	Record No.	Kind of animal.	Received from—	Result of inoculation.	Diagnosis by histological examination.	Persons or animals bitten.
1905.

June 16	614	do.....	Blacksburg, Va.....	do.....	do.....	Several dogs.

In the 10 positive cases in which the plexiform ganglia were sectioned there was only one case (No. 504) in which the lesions were not sufficiently marked to base a positive diagnosis without waiting two weeks for the rabbits to develop the symptoms, and in this case the dog was killed during the course of the disease. This demonstrates the necessity of allowing the animal to die naturally from the effects of rabies if an early diagnosis by means of a ganglia examination is to be assured.

Rabies has been quite prevalent, however, in the portion of Maryland adjacent to the Bureau Experiment Station, and several dogs have been tested at the station. It is believed that this locality is not more especially infected than many other places, but that the frequency with which rabies is found there within a small circumscribed area is probably due more to the careful attention given to the subject than to the more common occurrence of the affection.

The great variations in the histories, symptoms, and autopsy lesions of rabid dogs makes a diagnosis practically impossible without inoculation or microscopic tests. Our experience is such that we regard it as real wisdom to place under proper restraint at once every dog that shows abnormal symptoms of any kind. The restraint need not and should under no circumstances be of a cruel kind. It is much easier to terminate a temporary restraint after the dog has recovered than to correct the damage he could do if his affection proved to be rabies.

During the year three experiments were made by the Pathological Division in order to test the effect of filtration on the virus of rabies. The material used was taken from rabbits dead as a result of inoculation with street virus. The brain was removed, macerated in a mortar, and made into an emulsion with physiological salt solution. This emulsion was then mixed with a bouillon culture

of *Bacillus proteus vulgaris* of Häuser and filtered through a Pasteur-Chamberland B filter, the filtration being hastened by a vacuum of 25 inches. Cultures made from the filtrate remained sterile, and rabbits inoculated intracerebrally with the the material remained healthy, while the check animals inoculated in a similar manner with the nonfiltered emulsion died in every case with typical symptoms of rabies. We therefore conclude that the virus is nonfilterable.

Having established this fact, it was then decided to make routine examinations for the presence in the Purkinje cells of the cerebellum and in the cells of the hippocampus major of the so-called Negri bodies, which have recently been considered as the etiological agents of the disease. These bodies are cell inclusions found by Negri in 1903, and claimed by him to be protozoa and the specific cause of rabies. They vary in size from 0.5 to 25 microns in diameter, and while the filterability of these bodies may not be impossible, nevertheless the failure of the virus of rabies to pass through the fine meshes of a Chamberland B filter in the above-mentioned experiments seems to be additional proof of the etiological significance of these cell inclusions. They have been found varying in size, shape, and number in all the positive cases for which they were examined, but in none of those cases which were proved negative by other tests. As these examinations did not include all the cases that were received during the fiscal year the results have not been included in the above table; but it is apparent that the finding of Negri bodies in the brains of animals suspected of rabies is the most satisfactory and most rapid means available for the diagnosis of this disease.

MISCELLANEOUS INVESTIGATIONS OF DISEASES.

SO-CALLED BOTTOM DISEASE OF HORSES.

"Bottom disease," an affection of horses pasturing in the bottom lands along the Missouri River in Iowa and Nebraska, is under investigation by the Pathological Division. At the present stage of the work there appears reason for associating this malady with an affection of cattle known in Nova Scotia as Pictou disease, with Winton disease of horses of New Zealand, and with Molteno cattle disease of South Africa. The tissues examined present practically the same lesions as those described for the above-mentioned affections, namely, interlobular connective tissue hyperplasia, fatty infiltration of the liver cells, and hemorrhages into the spleen.

Pictou disease, Winton disease, and Molteno cattle disease have been investigated time and again in an endeavor to find a causative agent. All inoculation experiments have failed, and it has only been found of late that feeding experiments with certain weeds have given seemingly reliable results.

Pictou disease, occurring in Pictou and Antigonish counties, Nova Scotia, is now ascribed to the ingestion of a weed called ragwort. Winton disease is thought to be caused by a member of the ragwort family, *Senecio jacobææ*. The Molteno disease of South Africa is probably induced, according to recent investigations, by still another ragwort, *Senecio burchelli*. At least these weeds when fed to the

animals in their respective localities have produced diseases followed by a train of symptoms corresponding to those seen in the naturally induced disease. The post-mortem findings were also quite similar. It was also proved that these plants were most dangerous in the young state. Yet another variety known as *Senecio latifolius* was found to be deadly to stock.

Feeding experiments have been planned by the Bureau, and a study of the varieties of weeds found in the infected area of Nebraska and Iowa is now in progress.

A MOUTH DISEASE OF GOATS.

Within a week after the importation of 34 Saanen and Toggenburg goats from Switzerland, and while they were still held in quarantine at Simonsons Island, New York, a peculiar mouth disease simulating the virulent foot-and-mouth disease of Europe was observed by the superintendent of the quarantine station, who immediately telegraphed for the pathologist of the Bureau to make an investigation. On arrival it was found that at least 32 per cent of the flock was showing more or less advanced symptoms of the disease. After a careful clinical examination of all the affected animals, which included the taking of temperatures and the examination of the mucous membranes of the mouth, eyes, and nostrils, a diagnosis of impetigo labialis was made. This disease is also known as facial dermatitis, orf, and cursta labialis in England and Scotland, and teigmaul and mauigrind in Germany. Reports have been received of its prevalence in Canada, West Indies, and several sections of the United States.

The lesions in the early stages usually appears as an acute localized inflammation of the skin on the outside of the lips. This pimple-like formation is attended with much inflammatory swelling with a decided tendency to the formation of pustules. They dry and form crusts of a dark grayish color and of a fungoid appearance. The growths extend rapidly and become confluent in the course of a few days, forming a large diffuse scab, which is found when removed to cover a suppurative surface. Simultaneously with this the lips become tumefied, swelling to three or four times their normal thickness. The appetite usually remains good, but the animals feed with great difficulty owing to the sensitiveness of the affected parts. In the most advanced cases the scab extends from the lips up over the cheeks and eyes, and in some instances a muco-purulent nasal discharge appears, which adheres to the nostrils, and, together with the swollen condition of the surrounding tissues, causes a more or less complete occlusion of the air passages, resulting in labored breathing upon exercise. In some cases the lesions extend into the mouth, producing erosions on the inside of the lips, on the gums, and on the maxillary pad of the hard palate. These lesions, which are of a spongy consistency and present a papillomatous appearance, were especially noted on the smaller goats. Similar wartlike growths have been noticed on the teats and udders and on the legs, especially about the coronet and in the fold of the fetlock. The disease has been transferred to sheep and goats, but cattle appear to be insusceptible. Work is at present being performed with the view of determining the nature of the causative agent of the affection.

The lesions readily yield to a treatment of boracic acid, sulphur, and petrolatum, and one or two applications are usually sufficient to cure every case without complications. In fact, the disease appears to respond quickly to any of the common antiseptic solutions.

ROUNDWORMS IN SHEEP.

Throughout the more thickly settled regions of the United States one of the most important factors, if not the most important one, in the lack of success commonly experienced in sheep raising is the damage caused by internal parasites, and thousands of farmers in the eastern half of the United States have been driven to abandon the sheep industry because of losses among their flocks due to parasitic infection. The roundworms occurring in the alimentary canal are as a group probably the most important of the parasites of sheep, comprising no less than fifteen to twenty distinct species, some of which are both very common and decidedly injurious.

Because of their importance an investigation of these parasites has been undertaken by the Zoological Division with the intention of describing the various roundworms parasitic in the alimentary canal of ruminants in order that they may be distinguished from one another and determining as far as possible their life histories, from a knowledge of which practicable methods of preventing infection may be devised. Considerable progress has been made in this investigation, inasmuch as the principal facts in the life history of *Hæmonchus contortus*, commonly known as the stomach worm or twisted wireworm of sheep, have been established. This species, whose life history was heretofore unknown, is probably the most important of all the roundworms occurring in sheep. The eggs of the parasite are scattered over the pastures in the droppings of infested sheep or cattle. Under suitable conditions of heat and moisture they hatch in a few days, and within about two weeks the embryos develop to a stage in which they are enveloped in a cuticular sheath without openings. Prior to this stage the embryos are easily killed by freezing or drying, but after acquiring their sheath they are able to withstand continued and repeated freezing and will survive for many weeks in a dried condition. During wet weather and on dewy nights the ensheathed embryos crawl up stalks of grass or other convenient objects, ceasing their migrations when the humidity of the atmosphere falls below the point of saturation, usually coiling themselves into a spiral like a watch spring. They remain quiescent until the air again becomes moisture laden, when they resume their migrations, gradually working their way higher and higher. When grass thus infested is eaten by a sheep or other ruminant, the embryos continue their development, attaining full maturity in about three weeks. The foregoing facts are discussed more fully in Bureau Circular No. 93. Experiments are in progress to determine the necessary precautions to be taken in order to raise lambs free from parasites, particularly *Hæmonchus contortus*, the nodular worm (*Esophagostomum columbianum*), and the hookworm (*Monodontus trionocephalus*). So far the results of these experiments have been very encouraging, indicating the entire feasibility of raising sheep free from the species of parasites mentioned,

and more extensive experiments in various parts of the country in cooperation with State experiment stations and individual sheep owners are being planned.

GID IN SHEEP.

Further reports of the occurrence of the gid parasite in Montana have continued to come in since its discovery there in 1904, indicating that this dangerous parasite is becoming more prevalent in that State. In certain details the specimens of the parasite from Montana differ from specimens of European origin, and these differences, if found to be constant in all specimens, would show that the American form is of a different species or variety from that found in Europe. It is planned to investigate more fully this question of identity and to make a study of the distribution of the Montana parasite, the amount of damage caused by it, the relation of dogs and wolves to its propagation, and other points in its life history of importance from the standpoint of prophylaxis.

THE LARGE AMERICAN FLUKE IN SHEEP.

A destructive outbreak of fluke disease in a flock of sheep in Michigan during the winter was found to be due to the large fluke (*Fasciola magna*). While this parasite is common in cattle in various parts of the United States, it seems never to have been definitely reported in sheep prior to this time.

AUTOPSIES ON WILD ANIMALS.

The National Zoological Park furnishes quite an important percentage of the necropsies made by the Pathological Division. During the past year 171 animals from this source have been examined. In this collection are represented only the vertebrata, being still further limited to the series amniota. The list is pretty evenly and widely distributed among the three classes, reptilia, aves, and mammalia. If space permitted, a still further classification would be not only interesting, but important for study as showing the truly comparative nature of the pathologic studies thus carried on.

The post-mortem findings reveal the following:

Not diagnosed (failure due to decomposition and other unavoidable conditions), 18; traumatisms, 5; poisoning (arsenical), 9; old age, 1; diseases, 138. Of the last number there are accredited to the digestive apparatus 52 cases, apportioned as follows:

Liver, 5 (cirrhosis, 2; fatty degeneration, 2; necrobacillosis, 1). Gastro-intestinal tract, 45 (acute indigestion, 1; gastritis, 1; gastro-enteritis, 10; gastritis and intestinal hemorrhage, 2; enteritis, 14; enteritis complicated with peritonitis, 4; infectious enteritis, 3; infectious entero-hepatitis, 1; hemorrhagic enteritis, 1; colitis, 1; ulcerative colitis, 1; gangrenous intestines, 1; intussusception, 1; intestinal parasites, 3; carcinoma of the abomasum, 1). The gastro-intestinal and respiratory tracts were involved together in 2 cases. Enteritis and pulmonary edema, 1; pneumonia and catarrhal enteritis, 8; pulmonary edema, 1; pneumonia and pleurisy, 2; streptococcal broncho-

pneumonia, 1; verminous pneumonia, 1; lung parasites, 1; asphyxia, 1. The genito-urinary tract was involved 4 times—septic metritis and purulent peritonitis, 1; acute interstitial nephritis, 1; chronic interstitial nephritis, 2.

Bacterial diseases were specifically determined in the following 44 cases: Tuberculosis, 16 (pulmonary, 1; abdominal, 1; generalized, 14); infection with *Bacillus hydrophilis*, 2; with *B. proteus*, 17, including 1 case of infection with *B. proteus fluorescens*; infection with *B. enteritidis*, 2; with *B. pyosceaneus*, 1; hemorrhagic septicemia, 3; septicemia, 2; septico-pyemia, 1. Mycotic disease figures six times in this list, all being cases of aspergillosis (generalized, 4, 1 by *A. flavus*, 3 by *A. fumigatus*; pulmonary, 2, both by *A. fumigatus*). There were also noted 1 case of pseudo-leukemia, 1 of double goiter, 2 of osteomalacia, and 2 of filariasis.

DISEASES OF BIRDS.

The routine post-mortem work on birds by the Pathological Division has furnished the usual variety of diseases, with here and there the occurrence of some rare form. Traumatism claimed 2, both cases being instances of a foreign body in the gizzard. One duck and 2 chickens came as samples of a rather extensive outbreak of food poisoning. Three deaths by impaction—1 of the crop, 1 of the intestines, and 1 of the oviduct—and 1 case of invagination of the intestine with consequent bacterial invasion of the whole body were noted among chickens. Four chickens revealed on necropsy an intestinal catarrh due to intestinal parasites, and 5 pigeons brought in at different times showed the presence of the air-sac mite. Protozoal diseases were represented by epithelioma contagiosa or chicken pox, 6 chickens, and infectious entero-hepatitis, 1 turkey and 1 peacock. There was 1 case of peritonitis in a chicken due to ruptured oviduct, and 11 cases of enteritis, 6 of which were cases of "going light," 3 due to infection with *Bacillus enteritidis*—1 duck and 2 pigeons. Contagious catarrh or roup was found in 4 chickens, and there were 5 cases of pneumonia (4 chickens and 1 canary), 3 cases of infection of chickens with *Bacteria sanguinarium*, and 3 cases of pulmonary congestion (2 parrots and 1 canary), 1 parrot being a case of colibacillosis.

A few cases deserve special mention, one by reason of its transmissibility to man, one for its peculiar interest to sportsmen, and one as an interesting pseudo-tuberculosis.

Besides tuberculosis there are two infectious diseases that quite frequently destroy parrots—colibacillosis and psittacosis, the latter being an infection with *Bacillus enteritidis*. One of the cases noted above as pulmonary congestion was in a parrot, the bacteriological examination of which revealed a colibacillosis. This infection being so prevalent among parrots, it may well be asked whether the early removal of fecal matter from the cage and the prevention of its mixture with the food may not be an important factor in prophylaxis. It is quite certain that those who keep parrots can not be too careful in the matter of cleanliness.

Of still greater importance is psittacosis, a virulently infectious disease of parrots due to the presence of a *Bacillus enteritidis*

variant. Parrots imported into France in large numbers from the South American countries have developed this disease on the voyage, many of them dying and those that reached their destination being distributed through purchase or otherwise only to sicken with the same disease, and, further, to transmit their disease to human beings who fondled them or fed them from their own mouths or who cleaned their cages.

The development and maintenance of hunting preserves has until lately received little attention in this country. Interest in hunting is on the increase, and of necessity the number of preserves of such birds as give sport to the hunter will be likewise augmented. With this massing together in large numbers of birds and animals will come an increase in disease, or at least greater attention to the diseases of game. Grouse disease has long been known and dreaded by sportsmen in England. Various causes—damp weather, parasites, etc.—were assigned to it until Klein's work was published in 1889. He demonstrated the causative relationship of a number of the colon group of bacilli to this disease. Hitherto grouse disease has not been reported in this country, but during the past year a preserve near Washington, D. C., lost great numbers of partridges and an investigation of the disease revealed the cause to be a bacillus identical with that recognized by Klein in grouse disease.

A most interesting form of pseudo-tuberculosis in canaries was investigated. A canary fancier who had lost several birds brought two dead birds for examination. A small-sized mass of "canker" or yellowish, cheesy, pseudo-membranous exudate was found in the mouth. The spleen was enlarged to double its usual size, quite black where the original spleen tissue could still be seen, and so studded with caseous nodules as to be literally transformed into a tuberculated mass. The liver was studded with fine yellowish spots; the lungs and the kidneys were congested. Histologic examination of the tubercular organs gave an exact reproduction of Malassez and Vignal's tuberculoze zoogleeque, while there was recovered in pure culture from these organs as well as from the blood a bacterium which in plain broth grew as a streptobacillus. This bacterium proved pathogenic for mice, guinea pigs, rabbits, and pigeons by intravenous and subcutaneous injections and by inoculation on the irritated mucous membrane of the mouth. The spleen appeared to be the chief point of attack, with the liver and lungs next in the order named. The pathologic findings were identical in both canaries and in one brought in five weeks later. In this last bird the "canker" had diminished from a large mass to a minute speck under the application of weak boric-acid solution. However, unless such cases are noted very early and treated energetically, there can be little hope, as the germ appears to be quickly transferred by the lymphatics to the viscera. Streptobacillary pseudo-tuberculosis has not been noted before in this country.

During the year pulmonary mycosis in birds, which subject was comprehensively described in the Twentieth Annual Report of this Bureau, has been observed in 6 birds (2 white Indian cranes, 2 red-head ducks, 1 ibis, and 1 loon) autopsied at the National Zoological Park. In all these cases the affection appeared very extensive, especially affecting the lungs and the air sacs. It is quite evident

that the disease was contracted before the arrival of these birds at the park, as they all succumbed in from eight to twenty-five days after being received.

BEE DISEASES.

Since the latter part of the summer of 1905 the Pathological Division has been engaged in cooperative experiments with the Bureau of Entomology in the investigation of diseases of the honey bee, especially black brood (foul brood of Cheshire and Cheyne). A considerable part of the work has consisted in diagnosing samples of diseased brood sent to the laboratory from various parts of the country. As a result of the examinations it would appear from the negative result of many of our cultures that there are a considerable number of combs in which the larvæ have died as a result of chilling or other causes, and yet the appearance of the comb to the naked eye so much resembles the appearance of black-brood combs that a positive diagnosis was rendered almost impossible without recourse to a bacteriological examination. *Bacillus alvei* was isolated from a number of cases, and new foci of the disease have been located, especially those at Queen, Pa., and Palestine, Ill. Attempts were made in a small colony over a period of several weeks to reproduce black brood through the feeding of pure cultures of *Bacillus alvei*, but they have not thus far proved successful.

A few specimens of bees affected with bee paralysis were examined bacteriologically, and while several organisms were isolated from the specimens, no one of them appeared regularly in the different cases. The nature of this peculiar malady will receive further study. Several cases of supposed foul brood were also received, and anaerobic and aerobic cultures were inoculated in media made from healthy bee larvæ, but no conclusions have been drawn from the limited amount of work done with the bacteria thus obtained.

EXPERIMENTS WITH DIPS AND DISINFECTANTS.

STOCK DIPS.

Extensive laboratory experiments have been made in the Biochemic Division during the past year with various forms of stock dips with the object of increasing the efficiency of the dips now used for official dipping, and also for the purpose of determining the value of dips not now permitted for official use. The standardization of dips which are as a rule made of crude materials is a difficult problem and will no doubt consume considerable time, but sufficient progress has already been made to lead us to hope that we may succeed in our attempts to increase the efficiency of stock dips and at the same time to decrease their cost. The laboratory experiments have progressed to such a point that practical field experiments based upon results obtained in the laboratory have already been started by cooperation of the Biochemic and Zoological Divisions with the South Dakota Agricultural Experiment Station. Specially prepared dips are being tried on sheep affected with scab and are also being tested by comparing their effects upon scab mites removed from their host.

An effort has been made to modify crude petroleum so as to remove the possibility of the injury to cattle which sometimes follows the use of the plain crude oil as a dip. As a result of these experiments an emulsion was devised and subsequently described in Circular No. 89 of this Bureau. Reports from field experiments indicate that when properly prepared this emulsified oil possesses the virtue of the crude oil without its injurious properties. Further experiments with the emulsion are desirable.

DISINFECTANTS.

In conjunction with the dip experiments a similar line of work has also been undertaken with disinfectants. Fair progress has been made, and a detailed report of the results will soon be submitted for publication. The experiments have so far been directed chiefly toward the determination of the relative value of cresol-soap solutions and carbolic acid as germicides, and they point very clearly to the fact that cresol-soap solutions containing cresol in fixed proportions are more efficient germicides than carbolic acid in equal strength.

MISCELLANEOUS ZOOLOGICAL WORK.

PARASITES OF POULTRY.

The various species of tapeworms occurring in poultry in this country have been studied by the Division of Zoology, and a circular (No. 85) has been issued fully describing these forms and giving directions for treatment and prevention. Other parasites of poultry, some of them species new to science, have been studied, and the results are now being prepared for publication.

TICKS.

The study of the habits and life histories of ticks has been continued. Some unusual host relations of the Texas fever tick (*Boophilus annulatus*) were investigated and will be described in an article soon to be published. Some experiments with the chicken tick (*Argas miniatus*) were begun during the summer of 1905, with the special view of determining its relation to the so-called "tick disease" of chickens in the South, which is probably identical with the tick-borne spirillosis of South American chickens.

COLLECTION AND IDENTIFICATION OF PARASITES.

A large number of parasites have been collected at the autopsies of various domestic and wild animals, and numerous specimens sent in by correspondents have been identified.

INDEX-CATALOGUE OF MEDICAL AND VETERINARY ZOOLOGY.

The work on the card index has been continued during the year, and five parts of the Index-Catalogue of Medical and Veterinary Zoology, Bulletin 39, comprising the K and L authors, have been published.

SUPERVISION OF PEDIGREE RECORD ASSOCIATIONS.

A radical change has been made in the regulations of the Government regarding the importation of animals for breeding purposes. Heretofore the pedigree certificate of animals imported for breeding purposes had to show registration of sires and grandams. This requirement caused endless complaint from importers, and has been maintained only because the Department felt that in no other way could there be a reasonable assurance of pure breeding. Without a closer supervision of the books of record a more lenient requirement would be impracticable.

To improve the situation the Bureau considered the advisability of placing on the American herdbook secretaries the responsibility for the pure breeding of animals imported for breeding purposes, and requiring registration in an American book of record as the only evidence necessary to pass a breeding animal through the customs free of duty. Before taking definite action, however, the sentiment of the secretaries of American pedigree-record associations was ascertained, and it was found that the great majority of them were in favor of such a change. Accordingly, Bureau of Animal Industry Order No. 130 was revised and replaced with Bureau of Animal Industry Order No. 136, to take effect July 1, 1906. The new order requires all animals imported for breeding purposes to be registered in an American book of record before free entry will be permitted. The certificate of a custodian of such book of record that the animal is purebred and has been registered is all that is necessary for free entry. Where a breed has no book of record in the United States, the certificate of the Chief of the Bureau of Animal Industry must be obtained before the animals are passed free. A herdbook assistant to the Animal Husbandman of the Bureau has been appointed to devote his entire time to the work of supervising the certified American associations and the examination of pedigrees submitted to the Bureau for approval.

This change is a very important one and should result in good to the breeding industry. It will not only make secretaries more careful in the registration of imported animals, but will compel importers to register such animals, which has not been done in all cases, particularly with horses. If an imported animal is not registered, the breeding of its progeny is difficult and often impossible to establish, and therefore the intent of the law is nullified. But little objection has come to the Department from importers, and this has been largely from importers of horses, who claim that the fact that horses are not quarantined will make it difficult to get American certificates to the port of entry as soon as importations land; but this difficulty can probably be readily remedied. An importer can mail his foreign certificates to the American secretary far enough in advance of sailing to allow that officer time to record them and issue his own certificates and get them to the importer on landing.

The other features of the former regulations (Bureau of Animal Industry Order No. 130) are retained in substantially the same form.

The following numbers of books of record were on the certified list July 1, 1906:

Animals.	American books of record.	Foreign books of record.
Cattle.....	14	24
Horses.....	19	22
Asses.....	1
Sheep.....	20	13
Hogs.....	12	2
Dogs.....	1	4
Cats.....	2	1
Total.....	69	66

BREEDING INVESTIGATIONS.

HORSE BREEDING.

The horse-breeding work at the Colorado Experiment Station is progressing very satisfactorily. The stallion Carmon was bred to 26 mares in 1905, and got 24 in foal at the first service. His first crop of foals came last spring, and while it is too early to pass an opinion on them it can be said that they prove the horse to be a good investment as a sire. The stud has been increased by the purchase of two mares in Kentucky—one an inbred Mambrino King mare, and the other by Chester Dare out of a daughter of Harrison Chief. We have already some Harrison Chief blood among the mares in Colorado, but this is the first introduction of that of Mambrino King, unless the claim can still be made that Mambrino King was a grandson of Mambrino Chief, whose blood we have in considerable abundance. The female line from Harrison Chief is one of the most valuable known for the production of quality, style, and good conformation, and Mambrino King was one of the handsomest horses ever seen in an American show ring. For these reasons these mares should be of great value in the breeding work.

These purchases should be followed by others. There are probably a number of mares in the Colorado stud which will have to be discarded eventually as unfit for breeding purposes, and these should be replaced by others. Further, 20 mares is too small a number with which to do satisfactory work. The number should be increased. The experiment in breeding carriage horses has attracted the attention of the entire country and has caused much interest in the intrinsic value of the American horse. The Department has started a line of work which it is believed will be of the greatest value to American stockmen, and it should follow it up systematically and thoroughly. It is not the intention to recommend that the work should be increased to a point where it may become burdensome to the station, but the Department should be ready to purchase exceptionally good mares as opportunity offers, even if the number is increased beyond 20.

Work in breeding Morgan horses, in cooperation with the Vermont Experiment Station, was begun in June with the purchase of 7 mares and 2 fillies in Vermont and 2 mares in Kentucky. The object of this work is to prevent the loss of the Morgan blood and preserve the type, at the same time increasing the size over that

of the old Morgan. The mares were bought by a board composed of Prof. C. F. Curtiss, director of the Iowa Experiment Station; Mr. Cassius Peck, of the Vermont Experiment Station, and Mr. George M. Rommel, the Animal Husbandman of this Bureau. The board was very fortunate in securing mares of good size, uniformity, and quality, and strongly bred in Morgan line. The mares purchased in Vermont were sired by General Gates, Denning Allen, Bob Morgan, Young Ethan Allen (a full brother of Daniel Lambert), Rocky Mountain, and Gillig. Those bought in Kentucky were sired by Harrison Chief out of Morgan dams, and give a combination of blood lines which is of the greatest value.

The extension of the work in horse breeding is a matter of the highest importance. In Vermont, it is doubtful whether the resources of the station will permit an extension beyond what will come from the natural increase of the stud. In Colorado, however, the station is anxious to increase the number of mares materially, and the sentiment of the stockmen of the State is in harmony with the station's attitude.

A more important extension can and should be made by establishing experiments in Kentucky. Nowhere can the same amount of useful and valuable material be found. It is the center of the light horse breeding industry of the country; more carriage horses come from there than from any other State in the Union, and the project to establish a breed of American carriage horses will never be complete until the advantages of Kentucky are realized. The importance of this step warrants an increase in the appropriation for this purpose.

BREEDING ZEBRA HYBRIDS.

Unfortunately no progress whatever has been made in the breeding of hybrids between the Grévy zebra and the mare. The Zoological Park has not been able to breed the large zebra to mares, and a younger male, presented to the Department by Ras Makonnen, governor of Harrar, Abyssinia, through the courtesy of Hon. R. P. Skinner, consul-general at Marseille, broke his neck the first day he was turned out last spring by running into a woven-wire fence. The consent of the President has been obtained to use the large Grévy zebra at the Bureau Experiment Station. Quarters are being arranged and will soon be ready for occupancy.

FECUNDITY OF POLAND-CHINA AND DUROC-JERSEY SOWS.

An investigation of the fecundity of Poland-China sows was made by the Animal Husbandman of the Bureau, and the results were published in Circular No. 95 of the Bureau series. A similar investigation of the fecundity of Duroc-Jersey sows was included.

Results for Poland-Chinas were compiled from the American and the Ohio (now the National) Poland-China Records for the years 1882-1886 and 1898-1902. The total number of litters for the earlier period was 14,703 for the two records combined, and for the later period 39,812. The average number of pigs per litter for the earlier period was found to be 7.04 and for the later period 7.52, an increase of 0.48 per litter. The increase was somewhat greater in the American Poland-China Record than in the Ohio. These results are con-

trary to popular opinion regarding this breed, and show that the charges of diminishing fecundity are without warrant when a comprehensive number of litters is considered. They also show the value of the system used by the hog breeders' associations in requiring breeders to report the number of pigs farrowed in each litter, as it gives breeders data with which to increase the fertility of their herds.

The records for Duroc-Jersey sows could not be compiled for so long a period of time, only ten years being available with a comprehensive number of litters. The first five years (1893-1897) show an average size litter of 9.22, and the five-year period 1898-1902 an average size of litter of 9.27. The results for 1893 seemed to be abnormal, and if omitted there is a decrease of 0.01 per litter, too small to be of practical value. The results confirm popular opinion that Duroc-Jersey sows are more prolific than Poland-Chinas.

These investigations are being followed with studies of the inheritance of fecundity. Some results have already been obtained which show that the size of litter is affected, in part at least, by maternal inheritance and that the size of litter increases with the age and maturity of sows.

POULTRY BREEDING.

The cooperative investigations in poultry breeding at the Maine and Rhode Island experiment stations have been continued during the year. In Maine the principal object is to increase the egg-laying capacity of the flock of chickens. Already several hens have been found to lay more than 200 eggs in one year, and the results seem to indicate that the average egg yield of a flock can be increased by selection. A bulletin describing the methods used and the results so far obtained in this work has been prepared for publication.

In the Rhode Island experiments an effort is being made to breed turkeys that will be resistant to the disease commonly known as blackhead.

BREEDING EXPERIMENTS WITH SMALL ANIMALS.

Arrangements have been made to begin investigations in animal breeding by collaboration between the Animal Husbandry Office and the Experiment Station of the Bureau, using for this work the large stock of guinea pigs, rabbits, and other small animals at the station. Experiments to determine the effects of inbreeding will be started at once, and studies will later be made of crossbreeding.

FEEDING INVESTIGATIONS.

COOPERATIVE INVESTIGATIONS IN ANIMAL NUTRITION.

Investigations in animal nutrition in cooperation with the Pennsylvania Experiment Station were undertaken in 1898, when the construction of a respiration calorimeter for domestic animals was begun. The completion of this large and complicated apparatus occupied fully three years, the first experiments with animals having been conducted in the winter of 1901-2 and work having been continued up to the present time. These investigations are in charge of Prof. H. P. Armsby, director of the Pennsylvania station.

The investigations constitute a careful scientific study of the fundamental principles of animal nutrition. Starting with the food as a source of energy to the animal machine, they follow this energy through to its ultimate effect, determining how much escapes in the undigested residues of the food, how much is expended in the digestion and assimilation of the food, and what surplus remains to sustain the life of the animal or enable it to produce meat, milk, or work. The investigations are complicated, requiring the services of not less than seven men for the actual conduct of an experiment, and involve in addition a large amount of laboratory work and extensive computations. Hence it is not strange that the results seem slow in accumulating. The results thus far published include experiments upon timothy hay, red-clover hay, and corn meal, as to their relative values both for maintenance and for productive purposes. An outline of the results obtained has been published in Bulletin No. 74 of the Bureau of Animal Industry and in Bulletin 71 (revised) of the Pennsylvania station.

More important than the mere numerical results, however, has been the aid which the experiments have afforded in clearing up some fundamental points regarding the energy relations between the food and the animal. At the time when these investigations were begun the prevailing ideas were based largely on Rubner's earlier investigations, which were popularized in the United States by the writings of Atwater. It was then supposed that the so-called "fuel values" of feeding stuffs—that is, the amount of heat which they were capable of giving off in the body—was a measure of their nutritive value, and Rubner's factors for the fuel values of human food were used quite generally to compute the fuel values of the digestible nutrients of stock foods, a proceeding natural enough at that time, but which unfortunately seems to have proved less susceptible to change than the ideas on which it was based.

The investigations of Kellner in Germany and those at the Pennsylvania Experiment Station have amply demonstrated that this conception was erroneous, and that the real values of stock feeds are much less than their fuel values. That this should be true in the fattening or milk-producing animal is not so surprising, but that it should prove to be the case on a simple maintenance ration compels a material modification of our general conceptions and is of fundamental importance to the theory of the subject. The Pennsylvania experiments have shown, in the first place, that the real fuel values of stock feeds are less than the computed ones, and that, moreover, but a fraction of the real fuel value of stock feeds is utilized for any purpose in the body. In the three cases thus far investigated the real values for maintenance were found to range from 56 per cent of the fuel value computed from the digestible nutrients in the case of timothy hay to 67 per cent in the case of corn meal. On the basis of the digestible nutrients, 174 pounds of timothy hay appeared to be equal to 100 of corn meal for maintenance, while in reality 211 pounds were required. For fattening, the discrepancy was still greater, 275 pounds of timothy hay being required to equal 100 of corn meal.

A series of experiments, designed to study what effect the age and breed of the animal has upon the percentage of food energy utilized, has now been in progress for two years, but the results are not yet

sufficiently complete for publication. Later it is hoped that more extended data regarding the actual values of other feeding stuffs may be secured.

FEEDING COTTON-SEED PRODUCTS TO HOGS.

Experiments in feeding hogs with cotton seed and cotton-seed meal have been conducted at the quarantine station at Halethorp, Md., during the year by the Animal Husbandry Office, in collaboration with the Pathological and Biochemic Divisions, to test the poisonous qualities of these feeds. Hogs have been killed with cotton seed, cotton-seed meal which had been cooked, and ordinary choice commercial meal. When a varied ration was given in addition to cotton-seed meal death did not result so soon as where only one grain was fed. Bran and middlings were found to be little better than corn meal. Experiment-station results with corn meal have been confirmed, hogs dying in about four weeks from the time feeding cotton-seed meal commenced.

Post-mortem examinations developed the fact that many of the hogs die with very constant and characteristic lesions of the internal organs, viz, a severe hemorrhagic gastro-enteritis, congestion of the liver with parenchymatous degeneration, edema of the lungs, cloudy swelling of the kidneys, and oftentimes a well-marked dropsical effusion in the pectoral and peritoneal cavities, and occasionally in the pericardial sac. This effusion is occasionally light red in color and in most cases contains fibrinous shreds which cling to the visceral organs. The edema of the lungs is a very constant and marked lesion. Ulcerations or erosions of the gastric and intestinal mucosa are seen in the severest cases, and in long-standing cases emaciation is quite noticeable.

The experiment with bran and middlings will be repeated, and tests with fermented meal will be begun.

The Bureau is now in a position to raise its own hogs for this work, which will be a great advantage. Seven sows were bred last spring, the Maryland Experiment Station courteously giving the use of its herd boar. The Bureau has bought a boar pig, which will be used this fall, and a large number of sows will be bred.

BEEF PRODUCTION IN THE SOUTH.

The work in beef production in cooperation with the Alabama Experiment Station has been broadened by taking up collaborative work with Mr. John S. Kernachan, of Florence, Ala., who owns a large farm on the Tennessee River and for some years has been grading up from native cows by means of purebred Angus bulls. The experiment station is keeping records of his herd, under the direction of the Bureau, and undoubtedly good results can be obtained for southern farmers by showing the possibilities of beef production under farming conditions.

DIGESTION EXPERIMENTS WITH POULTRY.

The feeding portion of the second series of digestion experiments with chickens, conducted by the Biochemic Division, was practically completed during the previous fiscal year, but the analytical chemical

work required by the experiments was very great and has only recently been finished. The results should be ready for publication within a few months.

This second series comprises thirty-six individual experiments with corn, oats, and wheat, fed singly and in combination with each other, as well as with green feed.

WORK IN THE INTEREST OF THE DAIRY INDUSTRY.

During the year the work of the dairy division has been systematized and subdivided as follows: Butter investigations, market milk investigations, cheese investigations, southern dairy investigations, building and management investigations, laboratories, inspection of renovated-butter factories, and inspection of renovated butter in the markets. Each of these lines of work has been placed under the direction of an expert, the chief of the division, Mr. Ed. H. Webster, being personally in charge of the butter investigations, and the assistant chief, Mr. C. B. Lane, of the market milk investigations.

BUTTER INVESTIGATIONS.

In the latter part of the fiscal year 1905 plans were laid for extended investigations in the manufacture and storage of butter, with the object of rendering practical assistance to the butter-making industry by solving some of the difficulties encountered in the trade. This work was begun in June, 1905, and the first series of experiments continued throughout the fiscal year 1906. These experiments consisted in carrying in cold storage for several months, under varying conditions of temperature and storage, butter made under different conditions. The butter—about 5,000 pounds—was made at Monticello, Iowa, and Topeka, Kans., and placed in storage in Chicago, and was examined and scored during and at the end of the storage period.

Some of the questions as to which these tests were expected to give results were (1) the effect of pasteurization, (2) the amount of salt to be used, (3) temperature of storage rooms, (4) the use of cans hermetically sealed for storing butter, (5) the keeping quality of good compared with poor butter, and (6) the action of air in contact with butter in storage.

The butter was made from five lots of cream, three of which were sour when received at the creamery and two sweet. From each lot of cream two lots of butter were made, one pasteurized and the other unpasteurized, and part of each lot of butter was lightly salted and part heavily salted. The butter was packed in tubs and cans, some of the cans being only partly filled, so as to test the effect of air. It was then stored at temperatures -10° , $+10^{\circ}$, and $+32^{\circ}$ F., and at variable temperatures, part of each lot being stored at each temperature. The butter remained in storage about eight months.

The results showed that butter containing low percentages of salt kept better than butter of the same lot containing higher percentages of salt. Butter in full cans and in tubs at the lower temperatures scored about the same. At the higher temperature there was a slight difference in favor of cans. Butter in full cans kept better than that in cans only partially full. On the whole, butter

held at the lowest temperature kept best, both when in storage and after removal from storage. Butter made from cream received sweet kept well while stored at the two lower temperatures, and also after removal from storage, giving results wholly satisfactory. Butter made from cream received sour also kept well at the lower temperatures, but deteriorated rapidly after removal from storage, giving, on the whole, results which were very unsatisfactory. The conclusion is that light salting and low temperatures and the use of cream received at the creamery in a sweet condition give much the best results for storage butter.

A report giving the details of this experiment has been published as Bulletin No. 84 in the Bureau series.

The second series of experiments in the manufacture and storage of butter, which has not been completed, consists in the making of a quantity of butter at the Wisconsin Experiment Station and its storage in Chicago. Arrangements were made for the use of the Wisconsin station laboratories for the necessary bacteriological and chemical work.

Another unfinished line of work is the investigation in northern Wisconsin and Minnesota of the cause of fishy flavor in butter. The development of a fishy flavor in butter has been a source of trouble, and whenever reports were received that creameries were having this trouble an investigation was made with a view to discovering the cause, if possible.

A temporary laboratory was established at Bloomer, Wis., and large numbers of cream samples were tested bacteriologically and test churnings of butter made. While the cause of the fishy flavor has not yet been discovered, a number of probable causes have been eliminated, and a good foundation has been laid for continuing the work during the coming year.

Incidental to the last-mentioned investigations, studies were made of the cause and methods of prevention of mold in butter tubs. Experiments were conducted at points in Minnesota and Wisconsin and continued at the Iowa Experiment Station. Coating the tubs with paraffin was found to be the best method of prevention. A report of these researches has been written and will soon be published.

A study of the conditions that existed in the market regarding the sale of butter convinced the officers of the Dairy Division that something should be done to assist the butter makers in producing a better quality of butter than seemed to be finding its way to the markets. The work done by the State dairy and food commissioners and their field men indicated very strongly that there was such a need. Inspectors of the Dairy Division would visit a creamery and perhaps find everything apparently all right; they would see only the fresh butter. When this butter reached the markets, however, some ten days or two weeks later, it was very often found to be deficient in some respect. In order to bridge over this gap which seemed to exist between the factory inspection and the receipt of the butter on the market, an inspector was appointed in April to examine the poorer qualities of butter entering the New York market. This work was begun as an experiment to determine if some assistance could not be rendered to the creameries by giving them exact information as to the condition of their butter on its

arrival in the market. The work proved so advantageous that the butter board in Chicago requested the appointment of a similar officer for that market, and this request has been complied with. A system of reporting has been organized by which a statement of the condition of the butter is sent to the butter maker, a copy of it filed with the butter dealer who purchases this butter, and another copy sent to the office of the dairy and food commissioner of the State in which the creamery is located, for the use of his field inspectors. The dairy and food departments, particularly in Michigan, Minnesota, and Iowa, have indicated their desire to cooperate with the Federal Department of Agriculture in making this work a complete success.

CHEESE INVESTIGATIONS.

The investigations in the manufacture of soft cheese at Storrs, Conn., in cooperation with the Storrs Experiment Station, have been continued throughout the year. During the winter Dr. Charles Thom, mycologist connected with this work, spent two months abroad studying the manufacture of cheese in England, France, Germany, Switzerland, and Italy, and these studies have resulted in marked progress in the investigations concerning the manufacture of Camembert and Roquefort cheese. A bulletin (No. 82) dealing with the fungi which have to do with the ripening of these cheeses was issued during the year. The knowledge so far gained of these fungi and of the methods used and the conditions necessary in the manufacture of such cheeses indicates that it will be practicable to produce in this country soft cheeses of these types fully equal to the best European product, though there are some problems yet to be studied.

A study was made of the conditions surrounding the manufacture, storage, and sale of American Cheddar style cheese throughout the cheese manufacturing section of the country. During these investigations a locality was selected in which to make cheese for experimental curing and storage. A satisfactory place was found at Plymouth, Wis., where storage rooms suited to the needs of the work were secured, and a cheese factory about 3 miles from the town was induced to cooperate with the Dairy Division in the manufacture of cheese for storage. Mr. C. F. Doane, expert in charge of cheese investigations, spent three months in the summer of 1905 at this place, making cheese and studying the conditions in that part of Wisconsin. Between 2,000 and 3,000 pounds of cheese were placed in storage under different conditions of make and storage temperature.

In these experiments the usual amount of rennet, 3 ounces to 1,000 pounds of milk, was used for one-half of the cheeses, and twice the amount, or 6 ounces of rennet to 1,000 pounds of milk, was used for the other half. Two cheeses of each day's make were stored immediately in the curing room having a temperature of 32° F.; two in the curing room at 40° F., and two were cured in the factory curing room at about 65° F. Other cheeses were held one week to two weeks after making and were then stored at 32° and 40° F. In the case of both the low-rennet and the high-rennet cheese, that cured at 32° F. directly from the press scored highest, the average being 95 and 94.4 points, respectively, out of a possible 100. The cheese scoring lowest in each case was that cured entirely in the factory curing room at about 65° F. It was also shown in these investigations that taints

develop more noticeably in the factory curing room than in cold storage, and that taints and acidity were checked more by storage at 32° F. than at 40° F. It appears also that cold curing derives its value chiefly from its effect on what otherwise might be poor cheese. In view of the growth of the popular taste toward mild cheese it appears that the time is soon coming when all cheese, if ripened at all, must be ripened at low temperatures, and the sooner it is put into cold storage the better.

The details of these experiments, together with a digest of previous work on the same subject, have been published in Bulletin No. 85 of this Bureau. There was also published during the year a report on experiments in cold storage of cheese conducted by the Dairy Division in 1903-4.

The work at Plymouth and vicinity showed the need of a much larger and more comprehensive study into the methods of manufacture, ripening, and storage of American Cheddar style cheese, and toward the close of the year arrangements were made with the Wisconsin Experiment Station at Madison for cooperative work of this character, the station to furnish the services of an expert chemist and of an experimental maker. Cheese will be purchased on the open market and placed in storage, and cheese manufactured under known conditions will be placed in storage.

The Dairy Division is cooperating with the office of Experiment Stations of the Department in investigations as to the digestibility of Cheddar style cheese. The work has been conducted at Middletown, Conn., and will be continued for another year. It is hoped that these investigations will have a practical bearing upon the use of cheese as a food by the American people.

MARKET MILK INVESTIGATIONS.

During the year a study of the various markets was made and a bulletin was published on "The Milk Supply of Boston, New York, and Philadelphia." Investigations and studies were also started concerning the production, delivery, and distribution of market milk and the organization and working of milk sanitary commissions and other organizations tending to improve the quality of market milk. Plans are under way for organizing some system of scoring and registering dairies.

During the National Dairy Show in Chicago in February the Dairy Division conducted an exhibit of milk and cream. Samples were secured from 13 different States and from 45 different producers. Medals were awarded by the show association, and diplomas were given by the Department of Agriculture, for the exhibits which scored highest and kept best. This work attracted a great deal of attention and has stimulated a desire in a number of States to inaugurate systems of scoring milk and cream. A report has been prepared for publication as a bulletin of the Bureau.

During the year circulars were sent out to about 2,500 American cities asking for information concerning the milk supply and the regulations governing the distribution and sale of milk. About 1,400 replies were received, containing a great deal of material that will be useful in advancing the cause of good milk.

SOUTHERN DAIRY INVESTIGATIONS.

The first work in connection with the investigations of southern dairying was to make a careful survey of the present conditions in the South. With this in view various States were visited by Mr. B. H. Rawl, who is in charge of this work, and conditions existing in the towns and surrounding country were studied. Ample notes of these conditions were taken with a view to determining the best course for future work to improve conditions and promote the dairy interests.

This preliminary work has developed the following facts: In some cases herds were found producing as good results as are ordinarily expected in any section of America. At other places milk was produced as cheaply as in any dairy section in the country. On the whole there was an enormous demand for dairy products. Almost all butter and cheese was obtained from other sections, some cream being shipped a great distance. Condensed milk and cream find a great market throughout all the Southern cities. Silage is used to a very limited extent in the South, but in a few isolated cases silos were found to contain an excellent quality of silage. One of the great drawbacks to dairying in the South is the inferior grade of cattle found there. They are mostly descendants of the Jersey breed, but lack altogether any quality that characterizes that breed. It is probable that this poor quality of dairy stock is due, in large part, to the fact that the live-stock industry has been made unprofitable because of the presence of the cattle tick and the infection of Texas fever. The Southern dairyman does not know how to grow feeds cheaply for dairy feeding. In many cases the feeds that he has at hand are not used to advantage because of lack of knowledge of the proper feeding methods. There is great need throughout the South for education in improved methods of dairy breeding and feeding and milk production.

The investigations so far have shown that there is a great desire on the part of many Southern people to know more about dairying. They are anxious for something that will enable them to get away from the one-crop system. The action of Congress in appropriating \$20,000 for the extension of this work during the fiscal year 1907 indicates that its importance is beginning to be realized.

DAIRY BUILDING AND MANAGEMENT INVESTIGATIONS.

The large number of inquiries that comes to the Dairy Division for assistance in designing and constructing modern improved dairy barns and other dairy buildings resulted in the taking up of the study of buildings of this character. Circulars were issued stating that the Division was prepared to give assistance to a limited number of applicants for plans for barns and other dairy buildings, and many inquiries were received as a result. A large number of plans have been worked out and sent to farmers throughout the country. More have been sent to dairymen in the South than to any other section, though applications have come from every State in the Union.

The subject of silo construction has also received considerable attention. In August, 1905, three silos, representing three distinct types of construction, were built on different farms in the same neighborhood at Easley, S. C. They were built by the owners under the

supervision of the Dairy Division. One of these silos was of an entirely new form of construction, originated by Mr. G. H. Parks, the Division architect, which it is believed will prove to be very satisfactory. It consists of expanded metal, of a gauge sufficiently strong to withstand the pressure of the silage, and cement. The sheets of expanded metal were nailed to temporary studs and the lapping ends securely wired together. The inside was then plastered with 2 inches of cement and the temporary studs removed, after which the outside was covered with about one-half to 1 inch, completing a wall from $2\frac{1}{2}$ to 3 inches in thickness. As the silo was only partially filled the first winter, no conclusions as to the reliability of this construction have been drawn.

Another of these silos was built on what is known as the modified Wisconsin plan, which is described in publications of the Wisconsin Experiment Station and of many other stations. The third silo is known as the stave silo. In the latter a slight departure from the regular method of construction was made. The staves were spiked to each other at intervals of about 5 feet, so that the structure stood solid and firm even before the hoops were placed upon it. It is believed that this method of spiking the staves together is superior to the old method of putting up tongued and grooved staves.

It is the intention to study these three forms of silo as to their durability and practicability. Applications were received during the year for specifications and directions for building more than 75 silos in the South.

A circular (No. 90) giving a plan for a modern dairy barn, with suggestions that would enable a builder to use the ideas embodied in this structure in any form of barn he might wish to build was issued during the winter, and a large number of copies were distributed at the dairy show in Chicago in February. This circular was copied by nearly all the agricultural papers of the country and received favorable comment. Plans are gradually being worked out for a more complete publication concerning barn and silo construction.

Investigations into the management of creameries and cheese factories are being undertaken. The principal creamery and cheese sections of the country will be visited and the business features of the industries studied, including the organization of the creamery or cheese factory company, the equipment of such establishments, the kinds of buildings used, etc. The object of this line of work is to enable the Dairy Division to give expert information along these lines to those who desire it.

DAIRY LABORATORIES.

The Dairy Division has not heretofore maintained a dairy laboratory in Washington, the necessary laboratory work having been done in other laboratories of the Department or at experiment stations. It was decided, however, in the latter part of the fiscal year to establish a laboratory for the Dairy Division in Washington, and two rooms of the building used by the division were set aside and are being fitted up for this purpose.

RENOVATED BUTTER INSPECTION.

The inspection of renovated butter and of the factories producing the same, under the law of May 9, 1902, has been continued. Dur-

ing the twelve months ending June 30, 1906, 374 inspections were made at 67 factories, making an average of $5\frac{1}{2}$ visits to a factory, the greatest number of inspections made at any one factory being 9. These factories produced during the fiscal year 53,795,321 pounds of renovated butter, as against 60,164,783 during the previous year. During the fiscal year 1906 the following amounts of renovated butter were inspected for export: At Chicago, 6,353,881 pounds; at New York, 4,184,118 pounds, and at Boston, 467,538 pounds, a total of 11,005,537 pounds.

The general sanitary condition of factories has improved materially from past years, and there are fewer violations of regulations in regard to the affixing of labels and stamps as prescribed by the law and the regulations of the Department. As a rule the factory men are endeavoring to the best of their ability to comply with the law and the regulations.

Renovated butter has also been inspected in the markets with a view to detecting violations of the law and regulations. On evidence obtained by inspectors two prosecutions were brought against a dealer, which resulted in his conviction in both cases, a fine being imposed in one and both fine and imprisonment in the other. The court decisions sustained the rules and regulations of the Department of Agriculture in so far as they applied to the cases in hand.

Samples were collected in a number of cities where renovated butter was found to be sold in an illegal manner, and cases have been prepared for prosecution against two wholesale dealers in renovated butter for removing the marks, stamps, labels, etc., and putting the goods on the market under deceptive names. These cases have not yet been brought to trial. It is believed, however, that there will be no further question as to the right of the Department to control the way in which renovated butter shall be sold upon the open market, so as to prevent fraud upon the purchaser and the consumer.

FUTURE DAIRY WORK.

The lines of work already under way should be continued and several of them extended. For instance, it is proposed to take up the study of Swiss cheese in addition to the other European varieties now being investigated, and the southern dairy investigations should be enlarged as the work progresses. The building and management investigations have only begun.

The Dairy Division has been able to make but little headway during the year toward indexing dairy literature as proposed in the report for the previous year, but plans are made for carrying out the project. A comprehensive index of dairy literature would be of great value and assistance in the work of the division and to dairy writers and investigators, as there is no such index in existence.

The efforts of the Dairy Division so far have been mainly along the line of the handling and marketing of milk and the manufacture of milk products. The whole subjects of dairy husbandry, the production of milk, the influence of breed and feed on quality and quantity of milk, the encouragement of farmers to know more about their stock, and other important lines of work, are as yet untouched by the division, except that a beginning has been made for the year 1907 in the study of milk as it may be affected by the period of lactation and the breed of the cow.

Two new lines of work are planned to be undertaken during the fiscal year of 1908, namely, investigations in milk production and in the manufacture of condensed milk and cream.

In order to extend the present work and to take up the new lines of work that are indicated, a considerable increase in the amount of appropriation available for the Dairy Division will be necessary.

PUBLICATIONS.

Several of the publications issued or prepared during the fiscal year have already been mentioned. Besides these, the Twenty-first Annual Report of the Bureau for 1904 was issued, and the Twenty-second Annual Report (1905) was prepared for publication. These annual reports are volumes of several hundred pages, containing special articles and miscellaneous information relating to the live-stock industry and the work of the Bureau. Among other important publications prepared during the year are a bulletin on Tuberculosis of the Food-producing Animals, by Dr. D. E. Salmon (this work having been undertaken while he was Chief of the Bureau and only recently completed), and a revision of Bulletin No. 27, Information Concerning the Angora Goat, made in pursuance of a resolution of Congress.

The new publications issued by the Bureau during the twelve months ending June 30, 1906, were 70 in number, consisting of the Twenty-first Annual Report of the Bureau, the annual report of the Chief, 13 bulletins, 19 circulars, 3 Farmers' Bulletins, 31 orders and regulations, and 2 Yearbook papers, aggregating 2,099 printed pages.

NEEDS OF THE BUREAU EXPERIMENT STATION.

The work required of the Experiment Station has increased until the facilities, both as to laboratory and field room, have become inadequate. The addition of a second story to the laboratory building is greatly needed, and there is some doubt as to whether the current appropriation act confers authority for such work or for the erection of new structures of any kind. More land is also needed, not only to allow room for the proper arrangement and separation of animals under experiment with contagious diseases, but to provide for the production of green forage for the animals, which are necessarily confined to small paddocks. Increased space would lessen the danger of the accidental spread of contagion, as well as effect a large saving in feed bills, and the purchase of additional land is therefore considered the part of wisdom and economy. I recommend that Congress give authority for such purchase, also authority to make alterations to existing buildings and to erect new structures as necessity may arise.

PROPOSED EXPERIMENTAL FARM FOR BREEDING, FEEDING, AND DAIRY INVESTIGATIONS.

As the work in animal breeding and feeding progresses it becomes evident that the Bureau will need an experimental farm near Washington for investigations of this class, aside from the cooperative work being done with the State experiment stations. Experiments

in breeding and feeding have been carried on in a small way at one of the Bureau quarantine stations and at the Bureau Experiment Station for contagious diseases, but it is obviously very undesirable and unwise to keep animals for experiments of this kind on the same premises where animals are undergoing quarantine or where experiments are being made with contagious diseases. It therefore seems that the time is soon coming when the Bureau should be provided with a separate farm for investigations in breeding and feeding live stock and in dairying.

EXPENDITURES.

The expenditures from the appropriations for the work of the Bureau, with names of persons employed, are shown in the following statements:

Summary of disbursements from the different appropriations for the Bureau of Animal Industry during the fiscal year ended June 30, 1906.

[This statement includes accounts passed for payment up to and including November 19, 1906.]

APPROPRIATION FOR GENERAL EXPENSES.
